In addition to the title, [Rostami et al. \(2014\)](#) found having different words in the keywords than in the title was a predictor of the number of citations an article received. When considering your keywords, two are fundamental in MMR reporting. One keyword should be included that describes the type of mixed methods design. Another keyword should be included that describes the problem addressed. The remaining keywords should be relevant to the reader understanding the intent and context of the study. Editor-in-chief, [Villar \(2020\)](#) advises that authors should make sure they have suitable keywords so the paper will be among the first to appear when a future author wishes to make a citation. Keywords are also one of the many ways search engines provide accurate results. Therefore, choosing keywords carefully are not only necessary to make your work more discoverable, but are also valuable to journals as this helps increase readership, citations, and their Impact Factor ([SAGE Publishing, n.d.](#)).

Voice

When disseminating MMR, it's beneficial to engage the reader in your text, while maintaining a scholarly presence. When writing up mixed methods, many researchers are unsure what approach they should take regarding the author's voice. Typically, qualitative writing is written in first person and quantitative in neutral or objective third person language. The question becomes should you write your paper in one voice or separate the paper between a qualitative first person voice and quantitative third person voice. [Zhou and Hall \(2018\)](#) share that traditionally entire mixed methods reports have used third person only and argue for more inclusion of the first person. The standard use of the third person writing style effectively writes out the presence of the researcher and renders them invisible ([Lazard and McAvoy, 2020](#)). [Zhou and Hall \(2018\)](#) go on to explain that the mixing of first person and third person voices can be beneficial so that

work is not tied one-dimensionally in its descriptions, in its dissemination of results, but is open to new ways of perceiving the world ... [incorporating] ideas of multiple voices ... conjoining voices ... to juxtapose different perspectives and demonstrate the possibilities of mixing voices in a single text (p. 354).

No standard has been set on whether to use first person only, third person only, or a blending of the two. [McCurdy \(2021\)](#) exemplifies the dual voices in her transformative mixed methods dissertation exploring science identities as she explains first the quantitative approach in the more formal third person voice, then uses personal pronouns as she describes the qualitative approach.

Logistic regression was conducted to determine whether students' SIS and SRS predict their decisions to pursue science professions after college ... Based upon the transformative mixed-methods research design, I integrated the quantitative and qualitative components of the research findings for research question (pp. 95–100).

[McCurdy \(2021\)](#) continues this pattern throughout the methods and reporting sections. When deciding which voice to include in your writing, we recommend that you consider which voice will engage your reader in your text and create the desire to continue reading.

Introduction

The introduction section plays a key role in engaging the reader in the background of your research. It serves as a roadmap for your research study, one that a reader can easily follow and understand. The introduction should show the importance of your topic by reviewing, critiquing, and synthesizing the applicable literature to identify key issues; theoretical frameworks; clarify barriers, knowledge gaps, or practical needs; and frame the problem in its context. In particular, the introduction needs to convey the barriers in the literature that suggest a need for both qualitative and quantitative data ([Levitt et al., 2018](#)). It “foreshadows the need for a mixed methods approach by outlining the literature illustrating the complexities” ([Wu et al., 2019](#), p. 910). Fundamentally, after reading the introduction, the reader should be able to understand the topic, why it is important, and why you adopted a particular method or approach. For more information, see Onghena's chapter on research synthesis for literature reviews in this volume.

As you write your mixed methods paper, it may be helpful to visualize an hourglass that is broad at the top, narrows slightly, and then broadens at the bottom, representing the broad introduction, narrower methods and results, and broad discussion (See [Fig. 1](#)). With this in mind, the paper should then begin with the more general aspects of the topic, then narrow toward the more specific information needed to place it in context and flow fluidly to the purpose and rationale for the study including the “need and value for the use of a mixed methods research” approach ([Fetters, 2020](#) p. 258). You should concisely cover what's already known about your topic and then show the gap of what is unknown, explaining notable concepts needed for the reader to understand your rationale. Keep in mind that the overarching goal of your introduction is to make your readers want to read your paper. All of your writing should tie back into this introduction section. Therefore, we propose writing your mixed methods paper much like an artisan weaves yarn in and out to create a beautiful tapestry. Just like the tapestry integrates a variety of colors, so should the mixed methods researcher weave the colorful strands of qualitative, quantitative, and integrated knowledge (see [Fig. 2](#)).

Problem statement, research questions, and rationale for mixing

MMR studies raise a level of complexity and potential incongruencies that will need to be carefully navigated regarding paradigms and procedures (see Philosophical underpinnings of MMR, Shannon-Baker, in this volume). As in all research, but in mixed methods particularly, the research question is the foundation and focus of all methodological decisions and determines the combination or integration of approaches ([Ponce and Pagán-Maldonado, 2015](#)). Thus, the goal of the research questions is to build on and mutually complement the findings of each other. Buchholz (2019) explained that the

components should provide insights into a superordinate (integrated) research question, which should therefore be formulated in such a way that the components can also focus on corresponding sub-questions and provide insights that can be related to the overarching question, that is, they can be integrated (p. 134).

Thus, a mixed methods study should be driven to answer the research questions.

Typically, a mixed methods study will address three strands of questioning—a quantitative question, a qualitative question, and an overarching question that can only be answered by weaving the strands together to integrate results. Perhaps a researcher wanted to study the use of a teacher professional development series for promoting certain instructional skills. The overall research question may be “*How did the professional development intervention affect the competencies of the teachers?*”. This overarching question may be approached in a mixed methods manner using both quantitative and qualitative inquiry to identify and understand teacher competencies. Quantitatively, the researcher may want to ask to what extent did teachers implement the intervention with fidelity, was

Fig. 1 The basic structure of a mixed methods report.

there a significant difference between student outcomes for teachers who received the professional development compared to the teachers who did not? Qualitatively, the researcher may want to know what did teachers perceive as barriers and facilitators to

Fig. 2 Woven components of a mixed methods report.

implementation? By using mixed methods, the researcher is in a unique position to use the results to complement each other and thereby understand a broader spectrum of the professional development's impact.

As described in section **Framing your paper**, the strands should be ordered to reflect the type of mixed methods design used. You should provide a thorough description as to how the approaches to inquiry were combined regarding the objectives and mixed methods rationale and how the results were obtained from using the mixed methods design type where mixing or integration occurred (Levitt et al., 2018).

Methods

The methods section is your opportunity to share your step-by-step plan for implementation from methodological considerations to sampling and participant selection. Ideally, this section “provides sufficient information to guide other researchers to replicate the study, assess the outcomes, and compare the findings with other studies” (Jalongo and Saracho, 2016, p. 141) by the readers’ basic questions of who, what, where, when, how, and why. You should explain and defend the methodologies and methods in your data collection and analysis processes. What were the reasons for choosing each approach and why is integration necessary? A good rationale for your methods typically is as heavily cited as the knowledge base in the literature review section. Whether you choose a separate or interwoven approach, the methods section should address the integrity of the qualitative methods, quantitative methods, and integrated approach. For more information, see Leech and Donovan’s chapter on MMR sampling and data collection in this volume.

Research design overview

The research design overview provides a road map for the study methods, which leads to a sharper understanding of the data collection approaches and helps the reader to interpret the results more accurately (Ghasemi et al., 2019). The problem your research is addressing as well as your research questions will drive the design of your mixed methods approach. Your report should be laid out according to the mixed methods design selected. While Table 2 listed different typographies and approaches, Table 3 gives simple examples of the order in which you might report your research design based on Hollstein’s (2014) categorization of four overarching groups. Many mixed methods studies are much more complex and require multiple rounds of data collection, analysis, and integration requiring a more advanced approach to reporting. While authors have reported there are as many as 40 types of mixed methods designs, we focus on four simplified categories from which you may build a (a) sequential exploratory, (b) sequential explanatory, (c) conversion, or (d) fully integrated design. Hollstein (2014) explains these designs as.

A sequential exploratory design starts with a qualitative phase, which is then followed by the quantitative phase ... A sequential explanatory design, in contrast, starts with the collection and analysis of quantitative data, which is then followed by a qualitative strand ... Conversion designs are designs that involve the transformation of data of one type into data of the other type for purposes of analysis ... The fully integrated mixed design is a specific kind of multistrand parallel design ... that most closely meshes and integrates qualitative with quantitative approaches (pp. 10–13).

Creswell and Plano Clark (2018) share that if the objective is to explore a problem posed by quantitative data followed with qualitative data, the design will require a sequential exploratory quan → qual design. If this is your design, the structure of the report and sections that follow should start with quantitative information, followed by qualitative information, and finish with the mixed integration. If the objective is to explain a phenomenon posed by qualitative data with quantitative data, the design will require a sequential explanatory qual → quan design (Creswell and Plano Clark, 2018). If this is your design, the sequence of your reporting should be the qualitative information first, followed by quantitative, ending with the mixed integration. If you are reporting convergent, concurrent, parallel, embedded, nested, or other complex designs, the importance of the quantitative

Table 3 Examples of methods order based on MM research design.

Design	Sequential exploratory	Sequential explanatory	Conversion	Fully integrated
Methods section	Research design Quan: - Participants and sampling - Procedures - Analysis Qual: - Participants and sampling - Procedures - Analysis Mixed integration	Research design Qual: - Participants and sampling - Procedures - Analysis Quan: - Participants and sampling - Procedures - Analysis Mixed integration	Research design Can determine the order-based priority and weighting. Mixed integration	Research design Mixed integration - Participants and sampling - Procedures - Analysis

approach versus the qualitative approach should guide your decision for the sequence of reporting with the most important approach leading each section. For more information, see Tajima and Fetter's chapter on MMR designs, Merten's chapter on transformative designs, Creamer's chapter on integration, and Maxwell's chapter on designing integrative MMR in this volume.

Notation

Much as music has a specialized notation system for musicians, a notation system was developed to convey the MMR process. In this system, the four letters *quan* indicates the quantitative approaches, while *qual* indicates the qualitative approaches (see Creswell and Plano Clark, 2018). Upper and lower case (e.g., QUAN vs. quan) indicate priority and importance with upper case indicating priority and lower case indicating supplementary. Symbols indicate the flow of the research process with an arrow sign (e.g., →) indicating the sequence of the quan and qual, a plus sign (e.g., +) indicating quan and qual were conducted concurrently, parentheses (e.g., ()) indicating either quan or qual was embedded, and brackets (e.g., []) indicating there were a series of steps or studies within studies. Finally, an equal sign (e.g., =) indicates the purpose of the study. Adhering to this system assists the reader to understand your research purpose and process.

Conceptual models

As an author, you should be aware of the potential difficulty readers may have following the path of complex designs. Many readers find visuals helpful for understanding the processes, contexts, and procedures for the study and can help explain how things were woven together. Ghasemi et al. (2019) found the use of appropriate tables and figures helped authors to summarize large amounts of complex information of the study procedures. It is common practice in mixed methods to include a figure in a publication that maps the steps taken and conceptualizes the process of data collection and analysis (Creamer, 2018). A conceptual model can assist with framing and showing the reader a blueprint of the overall research design (Baran, 2020), highlight the point or points of integration (Schoonenboom and Johnson, 2017), and share the context in which a study is conducted (Plano Clark and Ivankova, 2016). For example, Fig. 3 shows Kattan's (2022) socio-ecological framework used to guide his complex mixed methods study on teacher evaluation in Saudi Arabia.

In complex designs, Nair (2020) advises the inclusion of innovative figures to show the timing, interventional frequency, and follow up of each step in your study. Furthermore, a side-by-side implementation table of qualitative and quantitative sources could include type and sources of data, location and timing of data collection, and from whom. For more information see McCrudden's chapter on visual displays in this volume.

Integrating mixing

Mixed methods studies have several layers of complexity (Poth, 2018). The complexity of a study not only depends on the number of components, but also on the extent to which they depend on each other (Schoonenboom and Johnson, 2017). As mentioned previously, the integration or weaving of both qualitative and quantitative should be carefully navigated. Therefore, for this section of the methods, you need to share your plan for integration. If you collected data from multiple sources, you need to clearly identify the sources of qualitative and quantitative data (e.g., participants, text), their characteristics, and the relationship between the data-sets. For the reader to understand the mixing, provide information on sequencing, weighting, and be clear on whether the data were collected simultaneously or sequentially.

Sampling

Qualitative sampling

There are five areas critical for ensuring the integrity and trustworthiness of the qualitative approach (a) researcher description, (b) participants, (c) researcher relationship with participants, (d) participant recruitment and selection, and (e) any other details specific to the qualitative approach chosen. You should include a description of your researcher position including your experiences, worldviews, potential bias regarding the phenomena and participants being studied, along with your plan for how you managed these influences. Referred to as reflexivity, this allows your research claims and conclusions drawn to be understood and evaluated in context (Lazard and McAvoy, 2020). Reflexivity is a philosophically driven methodology of self-reflection and introspection and is not a one-and-done activity; rather, it should be embedded in the entire research process from inception to dissemination to mitigate any impacts of bias on the study.

Regarding participants, you need to fully describe the number and characteristics of participants and other data sources paying special attention to any perspective influences on the data collected. The researcher-participant relationship, if any, needs to be disclosed. Additionally, you should include a detailed description of all recruitment processes and any protocols that you created for data collection. The reader should understand the type of sampling used, whether participants were provided any incentives or compensation, how the number of participants was determined, what ethical considerations were made, and how consent was attained. For more information, see Koro et al.'s chapter on qualitative sampling in this volume.

Quantitative sampling

There are four topics to report for quantitative approaches (a) sampling procedures and participant selection, (b) sample size, power, and precision, (c) measures and covariates, and (d) other details specific to the quantitative approach chosen. Participant recruitment should include the inclusion and exclusion criteria and any restrictions based on demographics, culture, or contextual considerations. Further, the procedures used to select participants should be described (e.g., systematic sampling, self-selection,

Fig. 3 Kattan's (2022) Socio-ecological framework of a mixed methods study of teacher evaluations in Saudi Arabia. Used with author permission.

purposive, etc.), along with the setting and locations for data collection, any agreements or incentives, and how you maintained and monitored ethical and safety measures. For sample size, power, and precision, include your intended sample size, how the sample size was determined, and how and if the sample size was achieved including the theoretical inferences for population-level power analysis or localized purposive sampling (Reischer and Cowan, 2020). All the primary and secondary measures and covariates collected should be reported including those not used. Finally, you need to provide the details specific to the quantitative approaches chosen (e.g., matching criteria, unit of assignment, unit of randomization, etc.).

Data collection

Next, full details of your data collection methods need to be provided. Leech and Onwuegbuzie (2011) counsel authors to provide detailed information about all data collection instruments and protocols used for both the qualitative and quantitative phases including

the developer of the instruments (with appropriate citations); the format of the instruments; when, how, and why they were administered; the context and focus of data collection; the duration of data collection; and information about the quality of the data collected (e.g., score reliability, score validity, interrater reliability) (p. 64).

For this section of the report, you ought to share your plan for data collection with enough detail for reproducibility (Reischer and Cowan, 2020). Moreover, as studies evolve, you may make changes that might confuse the reader. Reischer and Cowan (2020) advise researchers to "report details of methodology and decisions made throughout the research process; do not assume shared understanding with readers" (p. 4). A researcher's transparency increases the validity, credibility, and trustworthiness of the study.

Qualitative procedures

When reporting on qualitative data collection, there are five areas to address the (a) form of data collected, (b) origins and evolution of the protocols, (c) extensiveness of engagement, (d) how data were recorded and transformed, and (e) how the researcher managed their reflexivity. Qualitative procedures tend to be more flexible and subjective, so it is essential to explain the approach taken and the choices made. Qualitative data may be collected in a variety of ways including observations, interviews or focus groups, dairies, or journals, and even art forms, each requiring a different type of protocol (Creswell and Plano Clark, 2018). These could be adopted or adapted from a pre-existing source or created specifically for the study. It is imperative that any changes made during the data collection process are documented. In addition, the extensiveness of engagement, how data were recorded, and how data were transformed play a major role in understanding the integrity of the research results.

As transparency of your researcher position is important, details also need to be provided with how you bracketed your position throughout the data collection and data analysis process. Bryman (2016) found that researchers need to conduct a critical examination of their beliefs and assumptions, including the way those can potentially affect interactions and relationships with the people and content under study. If a researcher waits until the data analysis stage, there is the potential impact on the integrity of data collected. Shufutinsky (2020) suggested a researcher needs to self-bracket presuppositions and beliefs throughout the entire research process, so it doesn't open the potential for "previous experience, knowledge, and assumptions to take root and create presupposition in the early stages of the research, including in the design of the study" (p. 53).

Quantitative procedures

When reporting quantitative data collection, the areas an author needs to address vary depending on the quantitative approach. Seven basic procedures to consider are (a) the methods used to collect the data, (b) quality of the measurements, (c) instrumentation, (d) masking, (e) psychometrics, (f) conditions and design, and (g) data diagnostics. For valid and generalizable results, a description of your methods should provide enough detail for another researcher to replicate your study. Essential is an in-depth explanation of how concepts were operationalized, variables were measured, and detailed information on the instruments, tools, procedures, and materials used for data collection. Ghasemi et al. (2019) explained that the level of detail needed will depend on the type of quantitative procedures and the audience. They share that the author should include what the reader needs for understanding how the key findings were derived.

Mixed procedures

If integration of qualitative and quantitative data occurred during the data collection process, the author needs to provide a description of the integrated procedures. In most instances, researchers don't approach integration until the analytic phase of the study (Levitt et al., 2018). When the qualitative and quantitative components co-occur, authors may use their discretion in presenting the procedures, but are encouraged to do so in a way that presents a logical progression of the report narrative as well as including an audit trail to show the steps to data collection, analysis, and how it informs the overall study purpose (Merriam and Tisdell, 2016). It may be helpful to your reader to refer them back to the notation and conceptual model sections explained previously.

Analysis

The data analysis section can be one of the most difficult and one of the most rewarding experiences of MMR. The data analysis should link back to the study purpose, objective, and aims (Fetters, 2020). In the analysis section, your focus should be to assist the reader to understand your process for analyzing qualitative data, quantitative data, and the integration of the two. As you explain the analysis, help the reader to see how you wove the strands together, pulling new colors into your tapestry; remind your reader how they refer to the colors you integrated from the introduction section. Visual displays such as tables and figures are helpful to document both the process of and product of the analytical procedures. The structure of the data analysis will determine the structure for the reporting. If you took a separative approach and conducted the qualitative and quantitative data collection prior to integrating the analysis, the reporting will be separate as well. If you took an iterative and interactive approach thereby allowing the data to interact during data collection, then reporting of the data analysis will be integrated. Since most of the published standards highlight the independent analysis of qualitative and quantitative data followed by mixing, and to provide continuity to the process we have described so far, we continue the approach for reporting from the perspective of qualitative, quantitative, and then mixed. This segregated approach lends itself well to the joint displays recommended by many in the field. For more information, see Guetterman's chapter on joint displays in this volume.

Qualitative analysis

When writing up the procedures for qualitative analysis, you should share your data analytic strategies with enough detail to be fully comprehended by the reader. Levitt et al. (2018) emphasize that authors need to provide rationales to illuminate analytic choices in relation to the study goals. As mentioned in **Analysis**, this is an opportunity for you to weave aspects of the introduction section back into your paper as you discuss the qualitative analysis. A detailed description should be provided of the process of your analysis using the principles of transparency, including a discussion of the procedures (e.g., coding, thematic analysis). If not described elsewhere, this section should include coder selection, training, and collaboration. Next, include information on whether coding was conducted in an inductive or deductive manner, (e.g., coding categories emerged during the analyses or developed in advance). In addition, the units of analysis should be included (e.g., entire transcript, unit, text) and how you formed those units. If an analytic

scheme was used, include an illustration along with how and when the analytic scheme was determined. Finally, indicate what tools were used during the data analysis process, including any software.

Traditional for reporting qualitative data analytic procedures is the need to include a section on trustworthiness (see Cain et al. in this volume). With this in mind, it is critical that you share how you maintained methodological integrity and consistency. It should be clear to the reader that the claims you made from the analysis are warranted, grounded in the evidence, contextual, insightful, and meaningful. Share how you supplemented by checks added to data analysis to support the claims you made. Moreover, a description should be included on how you bracketed and managed your biases and perspectives. The reflexivity process is predicated on the broad questions of what the research process is and how you are influencing it from inception, through data collection, into analysis, mean-making, and dissemination (Lazard and McAvoy, 2020). When you acknowledge your personal bias and how you bracketed for them, it establishes a level of confidence in the reader and enhances the trustworthiness of your study (Daniel, 2018). Finally, you need to provide a description of how the study remained consistent or share any alterations you made including any changes due to ethical issues. For more information, see Miha's chapter on approaches to qualitative analysis in this volume.

Quantitative analysis

When reporting on the analysis of quantitative data, the areas you need to address vary depending on the quantitative approach. Fetter's (2020) suggested seven overarching steps to data analysis regardless of the approach (a) enter, clean, and address gaps or deficiencies, (b) frame the analysis in accordance with the study's purpose, (c) conduct a preliminary descriptive analysis, (d) use an organizational structure to report the findings, (e) check for inconsistencies, (f) organize findings for dissemination, and (g) interpret findings and write up results. The APA JARS-Quant includes 12 tables with details for the variety of quantitative approaches and recommends reporting the analytic strategy with sub-areas in each of the 12 tables.

Mixed analysis

Mixed methods data analysis strategies are "at the heart of methodological discussions about mixed methods" (Vogl, 2019, p. 551). In mixed methods, value accrues from both qualitative findings and quantitative results, and the integration of the two in a thoughtful way leads to greater mining of the data and enhanced insights (Levitt et al., 2018). Integration is the process of connecting, combining, and merging the qualitative and quantitative data for generating inferences and the mixed meta inferences of the conclusions drawn after the integration (Creswell and Plano Clark, 2018). Though there are instances where you may focus in on the specific strands from the colors of qualitative or quantitative, this is the opportunity to step back and look how these are being integrated to create your tapestry (see Fig. 4). For more information, see Vogl's Chapter on approaches to MMR analysis and Kuckartz de's chapter on using analysis software in this volume.

Integrating data offers the possibilities of answers that would not be accomplished by qualitative or quantitative alone, nor if these approaches were merely overlaid but not integrated (Oliveira et al., 2018). This underscores the importance for connecting the analysis back with the research question and goals and aligning this section with the need for justifications for the use of mixed method research studies.

Findings and results

Your results section should be concise but thorough and follow the order of the design referenced throughout the paper (Fetter's and Freshwater, 2015). You should begin with a sentence or two overview about the study and discuss only those findings that relate to the research questions and the purpose of the study. Here you should emphasize the major findings in a balanced progression, report both negative and positive findings, organize the data in tabular or illustration format, and provide associations, variances,

Fig. 4 Native American weaving an intricate pattern into a tapestry.

and magnitude of the findings with adequate interpretation and transparency (Meo and Eldawlatly, 2019). “Failure to adequately, transparently, and rigorously report findings has been described as a form of scientific failure” with “unacknowledged biases, inability to replicate due to missing information, or lack of clarity around context” that could potentially lead to preventing evidence to be put into practice (Wharton, 2017, p. 487). Worse yet, studies show that these missing components could be “dangerously misleading to policy decisions” (Kac and Hirst, 2011, p. 1872).

Qualitative findings

What you include for the qualitative findings will depend greatly on the approach taken in your study. Each qualitative methodological approach has its own style of writing, or storytelling (Schinke et al., 2020). You should present research findings in a way that is compatible with the study design and demonstrate the credibility or trustworthiness of your study. Daniel (2018) explained that trustworthiness requires establishing that findings are credible, relevant, and congruent thereby giving the reader confidence that “the findings reflect participants views outside of researchers’ personal opinions” (p. 265). Often, synthesizing illustrations (e.g., diagrams, tables, models) are useful in organizing and conveying findings. You may decide your study requires separate illustrations of your qualitative findings or you may choose a side-by-side visual to show the qualitative, quantitative, and mixing.

Quantitative findings

Much of what should be included in the quantitative findings will depend inherently on the quantitative approach taken in your study (e.g., the statistical output, missing data, model estimation, variance and covariance, etc.). Annesley (2010) shared that a valuable concept for you to remember is that data and results differ. Data are usually presented in tables and figures and results are statements in the main text that summarize or explain what the data show. In general, though, many researchers take the opportunity to show their quantitative findings with visual displays. These can assist readers to grasp, comprehend, and remember information (Jalongo and Saracho, 2016). The most effective visuals are self-explanatory allowing the reader to see trends, relationships, outcomes, categories, or general experimental parameters (Annesley, 2010). You should also display data in an order that makes logical sense to the viewer (Evergreen and Emery, 2016). However, close attention should be made to ensure the data type and visualization are compatible. Müller et al. (2012) warn that badly chosen visualizations can compromise the truth of academic reporting.

Integrated mixed methods findings

By the end of your report, the data analyzed from the qualitative and quantitative approaches should be integrated in such a way as to provide a fuller understanding of the phenomenon under study. Creswell and Tashakkori (2007) seminally shared that “integration might be in the form of comparing, contrasting, building on, or embedding one type of conclusion with the other” (p. 109). Leech et al. (2011) emphasize the importance of the context stating it’s essential for the content “to be delineated for the reader so that it is clear how the quantitative and qualitative findings relate and the extent to which meta-inferences can be made” (p. 21). Much like our tapestry, Fetters and Freshwater (2015) share that the results “may be structured and described using a weaving pattern where the quantitative and qualitative findings presented together thematically with a weaving back and forth of quantitative and qualitative data by theme or domain” (p. 212).

In their editorial on publishing methodological MMR, Fetters and Freshwater (2015) shared three ways for demonstrating integration of illustrative quantitative and qualitative results: narrative, data transformation, or joint display presentation. A narrative format is simply a text-based account of your findings and may be shown separately or integrated. In data transformation, qualitative data are transformed into quantitative data or the opposite with quantitative data transformed into qualitative. A joint display allows the quantitative and qualitative data to be observed in a side-by-side display in such a way that helps to make mixed interpretations that would not otherwise be known if the researcher conducted a qualitative-only or quantitative-only study (see example in Table 4). You should avoid discussing or interpreting the results until later in the discussion and conclusion section.

Discussion and interpretation

The discussion piece is one of the most valuable components of your paper, it provides clarifications on synthesis of your findings, any issues, and includes an interpretation of the results and recommendations for practice. A good discussion section leaves the reader with an understanding of “why the researcher took the time to do such a complicated study and can help to pull together findings, which may otherwise appear contradictory or unrelated” (Bronstein and Kovacs, 2013, p. 359). Your interpretations should go “beyond first-level results or literal description of observed behaviors, patterns, and themes from analysis” (Johnson et al., 2020). Further, in discussing your mixed methods study, your primary challenge is to provide a complete and thorough exploration of how specific results relate to each other, contribute to answering the research questions, and achieve the primary purpose of the research endeavor. If you have presented your study with Figs. 2–4 in mind, the discussion section should relate the findings with that to the introduction. It should take the strands of qualitative and quantitative data to weave together a beautiful tapestry of research questions, study design, data collection and analysis, and interpretation of results. While readers may come to the same conclusions as you after reading the findings, a beautifully woven discussion can assist the reader to visualize and more fully understand the delicate interlacing of the data. This is especially crucial when the findings are complicated or contradictory (Bronstein and Kovacs, 2013). If done well, you will have reported out in such a way that is both understandable to the reader and has been woven

Table 4 Example of a joint display for a mixed methods study on high school dropout.

Theme	Quan results	Qual results	Mixed interpretation
Dropout mindset	98% of students who dropped out from XYZ school in 2021 tested at below proficiency in at least two academic areas in 4th grade	Students shared they struggled academically even in elementary school. They never felt they could “catch up” “so what’s the point?”	Dropout mindset begins early
Dropout absenteeism	98% of students who dropped out from XYZ school in 2021 were absent more than 10 days	Students shared many reasons for being absent from “I feel like others think I am just lazy but I am not” and “my dad works 3rd and I couldn’t leave the house I’d miss the bus and didn’t have a ride to school” to “my mom needed me to stay home with my baby sister so she could work” to “I had to get a job to help pay the bills”	Dropouts feel they are perceived as lazy or stupid, but often they aren’t in school because of other more pressing needs or obligations.

together like a beautiful tapestry. The final sections of your paper should contain an ending that gives the reader the utmost satisfaction and that their time reading your manuscript was well spent (Meo and Eldawlaty, 2019).

Responding to the reporting limitations for mixed methods

A pervasive issue with reporting MMR is the limited space given to authors in many dissemination paths. For example, many academic journals enforce strict word limits, which often are insufficient for the descriptions required in mixed methods studies (Brown et al., 2015). Bazeley (2015) found that journals “often have 3000–5000-word limits on the length of articles” (p. 301). She goes on to recommend the following strategies to deal with this problem (a) publish a methodological article first to describe the approach and data sources, then draw on this for reference in later articles, (b) provide an overview paper first and then a *wrap up* paper drawing on the mixed methods findings at the end, (c) focus separate papers on specific aspects of the study bringing together all relevant sources for this issue, or (d) seek out journals that allow for longer articles. Another approach that Brown et al. (2015) share is to take advantage of the option for including supplementary materials online to include more details regarding methods and rigor. Creswell (2015) recommended generating three separate papers from the mixed methods study: quantitative, qualitative, and *overall* or adding a methodological paper discussing unique mixed methods procedures making sure to observe the sequence in publishing separate papers and providing cross-references from one paper to another to establish consistency and reduce the length. Careful self-examination of your design, purpose, and context is essential before deciding your approach.

Final thoughts for reporting mixed methods

With a trend of increasing use of MMR by education researchers to investigate complex issues within the field (Crawford and Tan, 2019), there is a need for integrity in reporting MMR. While there is debate in the field as to the specific structure or framework to use when reporting mixed methods studies, we have outlined an approach to assist the writer to include the critical components of mixed methods reporting. Researchers, such as Creamer (2018) have suggested full integration with the qualitative, quantitative, and mixed methods woven together throughout reporting. There is a concern in the mixed methods field that the pressure to conform to a specified set of designs has led to too little attention on its products (Guest, 2013), where most “designs show the qualitative and quantitative phases as quite self-contained” (Creamer, 2018, p. 297). There is a small but growing number of researchers calling for more integrated methods throughout the research process. Whether you create reports where each approach is highlighted separately or interwoven throughout, the items outlined in this chapter are imperative to ensure trustworthiness and reproducibility of your study. As mixed methods researchers in the field of education, the focus needs to be on the dissemination of our research in ways that readers can fully understand and act, especially regarding wicked problems. With such attention to detail, we have the potential to improve our research processes, educational environments, and ultimately outcomes.

Joint displays provide a visual method of facilitating the integration of qualitative and quantitative research (Guetterman, Fetters et al., 2015b). Joint displays have emerged as one strategy to report integrated results in mixed methods research. As presented in publications, theses, and dissertations, and other reports, joint displays typically consist of a table or a figure that presents qualitative and quantitative data, methods, or results. Recently, researchers have stated to use innovative joint displays that include graphs, charts, images, and other figures (Guetterman et al., 2021). Ideally, joint displays depict the outcome of integration, such as the development of meta-inferences, the generation of follow-up studies, or the building of an instrument. However, joint displays are increasingly being used as a method to integrate qualitative and quantitative research, rather than merely as a results presentation (Fetters and Guetterman, 2021).

Numerous types of joint displays have been identified in the literature. The most common type is a side-by-side display that juxtaposes qualitative and quantitative results along with meta-inferences from the integration of the two. Another type is a statistics-by-themes joint display that arrays themes as rows and statistical results as columns. While articles and chapters have cataloged different types or styles of joint displays (Guetterman, Fetters et al., 2015b; Plano Clark and Sanders, 2015; Younas et al., 2020) and presented their usage by design (Guetterman, Creswell et al., 2015a), little has been written about selecting a joint display based on a research question, purpose, or aim. For clarity, the term *intent* will be used to generally refer to research questions, purposes, or aims. The intent might be thought of as what is meant to be achieved through the integration of qualitative and quantitative research. Although intents and designs are highly interrelated, linking joint displays to their intent overcomes the fact that researchers use different design typologies. Uncoupling joint displays from specific research designs can considerably broaden their usage and unlock potential.

Mixed methods research is conducted in educational disciplines, such as teacher education, educational psychology, and cognition and learning. Moreover, scholars conducting educational research in various professions are increasingly using mixed methods approaches. For example, mixed methods research has been applied to engineering education (Crede and Borrego, 2013; Howell Smith et al., 2019), health professions education (McLaughlin et al., 2016; Schifferdecker and Reed, 2009), and accounting education (Lamprecht and Guetterman, 2019) to name a few. Research on education in the professions and other fields often layers on additional complexity and makes the need to integrate qualitative and quantitative research even more compelling. The methods of integration become even more salient. Critiques of mixed methods research in many of these fields have identified weaknesses with integration specifically (Institute of Education Sciences Technical Working Group, 2015; Plano Clark, 2019). Failing to achieve meaningful integration is so important because it limits researchers achieving the full potential of mixed methods research. Joint displays provide on potential solution for achieving integration. Next, I will examine some common strategies for integration in mixed methods research before discussing how the strategies can be applied through joint displays. However, relatively little literature has addressed the use of joint displays for reporting integration in educational mixed methods research. Even less literature has discussed the use of joint displays for mixed methods analysis in educational research.

To summarize, joint displays are emerging as a method of integrative analysis in addition to a way to report results, yet relatively little literature has linked joint displays to their intent, and few studies have examined joint displays from the perspective of educational research, which often intersects multiple interdisciplinary fields. Therefore, the purpose of this chapter is to discuss and advocate for the use of joint displays as an integration method in mixed methods educational research. This chapter presents templates for different types of joint displays as a starting point and cites examples of joint from educational research whenever possible. To achieve that purpose, this chapter will situate different types of joint displays based on the intent for integrating qualitative and

quantitative research. Before discussing joint displays, it may be helpful to review several major approaches to integration in mixed methods research.

Approaches to integration

Integration is the defining feature of mixed methods research that distinguishes it from monomethod and multimethod approaches, by most definitions. Integration refers to the interface of qualitative and quantitative research or where the two come together (Creswell and Plano Clark, 2018). Integration leads to something new: (1) new insights called meta-inferences that researchers identify through integrative analysis, (2) new follow-up phases of research that are systematically informed by a strand of research (e.g., results from a quantitative phase inform a subsequent qualitative phase), or (3) new data collection instruments systematically developed by a strand of research (e.g., results from a qualitative exploratory phase inform quantitative instrument development).

Integration can occur at multiple levels of research, such as integrating multiple philosophical worldviews (Johnson, 2017), intersecting more than one research design (Plano Clark and Ivankova, 2016), and thinking from a mixed methods perspective to ensure integration at all aspects in fully integrated mixed methods research (Creamer, 2018). For the purpose of this chapter and discussing joint displays, I will focus on methods of integration and discuss several of these methods below.

Mixed methods researchers have discussed and employed numerous methods for integration. These methods fall into several broad categories: (1) integrative analysis of qualitative and quantitative data or results to generate new insights, (2) sequential integration in which qualitative or quantitative results inform the methods of the other strand, (3) data transformation to convert one type of data to another for further analysis, or (4) hybrid approaches such as applying both qualitative and quantitative analysis methods to the same dataset and integrating results. Researchers often use multiple methods of integration in a single mixed methods study. For additional reading on integration, Schoonenboom presents different strategies for integration (see 11,045. Ten mixed methods integration strategies for obtaining a detailed understanding), Vogl reviews analysis of mixed methods data (11,048. Strategies to integrative mixed methods analysis), and Kuckartz discusses the use of software for mixed methods analysis (11,049. Mixed methods analysis software).

Integrative analysis of qualitative and quantitative data or results to generate new insights

One of the prevalent methods of integrative analysis is the analysis of qualitative and quantitative data or results together to generate meta-inferences. One type of this integrative analysis is merging to compare qualitative and quantitative results in similar domains or concepts, to assess whether they are convergent, divergent, or expand understanding and to identify new meta-inferences from the integrative analysis (Fetters et al., 2013). Pluye and Hong (2010, 11046. Convergence and divergence in mixed methods research) discuss ways to handle convergence and divergence in mixed methods research.

One specific type of this process is *following a thread* that consist of conducting separate analysis of each strand's data, identifying an analytic domain (i.e., the thread) based on the literature or research question to examine in each dataset, developing a multi-faceted understanding based on findings in each dataset, and iteratively conducting analysis and synthesizing threads. For example, White and colleagues examined the roles of racial identity, science identity, science self-efficacy beliefs, and science achievement among African American students attending historically Black colleges and universities (White et al., 2019). They used a convergent mixed methods design in which qualitative and quantitative data were analyzed separately and then merged for a more complete understanding. Guided by Critical Race Theory, a science identity model, and self-efficacy theory, they merged findings to examine whether the qualitative results corroborated the quantitative results, and when they were corroborated, used the qualitative data to expand on results. For example they explained the significant relationship between science identity and self-efficacy variables "as an interaction between recognition and mastery experiences (White et al., 2019, p. 67).

Another method of integration is to interrelate qualitative and quantitative results, such as examining statistical patterns by theme or examining thematic patterns by levels of a variable. For example, a study examining differential effects of an educational intervention to improve communication examined thematic differences for the high, middle, and low performing learners (Guetterman et al., 2019). A key meta-inference from integrative analysis was that for the group with the worst quantitative outcomes at post-test, their qualitative data indicated less motivation to learn more and less interest in learning about communication.

Sequential integration in which qualitative or quantitative results inform the methods of the other strand

Connecting is a method of integration through which the results of one strand of research inform the sampling of the other (Fetters et al., 2013). Connecting is a sequential type of integration because the results of one phase are needed to inform the next. Qualitative results could be used to help plan quantitative probability sampling such as identifying what characteristics would be important in a stratified sample. More common is beginning quantitatively and using the results to identify a purposeful sample for the qualitative follow-up. For example, researchers might use quantitative results to find individuals or sites that meet characteristics (e.g., differential performance levels of students, teachers, schools, or other systems), to find outliers, or to identify participants based on intervention outcomes. McCrudden and McTigue (2019) used quantitative results about high school students beliefs about climate change to identify participants to invite for interviews.

In *building* integration methods, the results of one strand of research inform the data collection of the other strand. Building is also a sequential type of integration. In a design that begins qualitatively, the results could be used to systematically build a quantitatively instrument, to adapt an instrument ensuring contextual relevance, or to identify variables for a follow-up quantitative phase. Alternatively, when a mixed methods design begins with a quantitative phase, those results could be used systematically to build an interview guide or focus group guide. For example, researchers studied teachers' integration of cultural content and heritage language into their classrooms and Latino students math achievement using an explanatory sequential design (Matthews and López, 2019). They wrote questions the follow up qualitative phase based on the quantitative survey items to further expand on the quantitative findings and learn how they implemented specific classroom practices.

Data transformation to convert one type of data to another

Data transformation is the concept of converting one type of data into another and integrating the transformed data. Quantitative data could be transformed to qualitative by adding a description or a narrative account to quantitative results like clusters, factors, or profiles (Bazeley, 2018). Transforming qualitative data into quantitative is more common and involves converting qualitative data or results into counts or binary variables (Bazeley, 2018). For example, a binary variable can denote whether a code, category, or theme was present. The now quantized data can be analyzed with simple or advanced statistics such as structural equation modeling (Newman and Constantinides, 2021) or other techniques. Hitchcock et al. (2021) provided an example of examining the implementation of a formative assessment system in kindergarten classrooms by a US state education agency. They integrated quantitative school data with quantized focus group data that identified whether schools had implementation problems and analyzed the data using hierarchical linear modeling to identify predictors of poor implementation (Hitchcock et al., 2021).

Hybrid approaches

Researchers have identified numerous hybrid approaches, also called inherently mixed methods approaches to analysis. Examples of these hybrids include conducting ethnographic analysis, case study analysis, and natural language processing of text data. An inherently integrative approach is ethnographic decision models that are used to understand decision-making processes. In one method, qualitative methods are used to gather decision criteria and then to develop a structured elicitation instrument to develop a preliminary model (Ryan and Bernard, 2021). The model is further developed and tested through mixed methods research. In another hybrid approach, case study typically involves collecting multiple forms of data, linking data sources, and analyzing data to better understand the case. When the data involve a combination of qualitative and quantitative and their integrative analyses, the case-oriented analysis is inherently a mixed methods analysis (Bazeley, 2018). Finally, natural language processing applied to a corpus of text can be an integrative analysis when augmented with human coding (Guetterman et al., 2018). In this method of integration, the largely quantitative analysis identifying phrases and assigning meaning is compared with traditional human coding of the text to develop a better understanding of text such as open-ended survey responses, text message survey responses, or written records (Chang et al., 2021).

In this brief review of integration methods, only select methods that are commonly applied were discussed. Learning other approaches to integration may be helpful in addressing research questions. For each of the approaches discussed, the development joint displays is a way to visually facilitate the integration of qualitative and quantitative research. The remainder of this chapter will focus of guidance for using joint displays generally and advice of selecting a joint display based on its intent.

Overarching guidance for using joint displays

Before discussing specific joint displays, this section provides broad guidance for their selection and use. First, I encourage you to think about the research question to be answered, the aim to be addressed, or the specific integration need to be conveyed through a joint display. In other words, what is the intent of the joint display? Later in the chapter, I will cover information about intents for a mixed methods joint display to help select one or more that may be most appropriate for your study. Consistency between the joint display (i.e., what type, what is included) and its intent is important for a reader.

Second, carefully consider what you want to communicate to the reader. The joint display can be used to display integrated results only or to walk the reader through integration steps, such as the development of meta-inferences or the systematic development of an instrument from qualitative findings. In addition, you might consider how to best communicate to the reader. For example, are numbers best displayed or would a chart or graph more easily communicate results (Guetterman et al. 2021)? Perhaps, grayscale or color coding related qualitative and quantitative results would assist with readability.

Third, developing a joint display is a process and creating the joint display itself might be your method of integration (Fetters and Guetterman, 2021). Termed joint display analysis, the process is a method to break down the relatively complex cognitive task of integration. Joint display analysis involves aligning related qualitative and quantitative concepts, considering what to include (e.g., text in cells of table or figures), and developing meta inference. Because the development often involves continual revision and refinement, the process can be incredibly helpful for conducting integrative analysis.

Fourth, it might be helpful to think broadly and innovatively about joint display development. Joint displays have been described as a data display or a way to show the integration of qualitative and quantitative data. I intentionally use a broader

definition of joint displays as a visual means to represent and facilitate the integration of qualitative and quantitative research. The rationale for this broad definition is because joint displays can be used to indicate how data are integrated, how results are integrated, or how results are integrated to inform methods of the other strand of research. The chapter provides examples of these different types of integration in the discussion of joint displays by intent below.

Common intents for using joint displays

Other articles have examined joint displays by mixed methods designs; this chapter takes a different approach and examines five intents for using a joint display and pair each intent with a template joint display. The reason for presenting joint displays by intent is because types of joint displays can often be used across multiple designs—they are not mutually exclusive. Here, I discuss using joint displays for (1) comparing qualitative and quantitative results, (2) relating qualitative and quantitative results, (3) connecting to identify samples, (4) building data collection instruments, and (5) explaining variation in outcomes. The list of intents is not exhaustive but represents common uses for joint displays. The following sections include a template as a structure for the joint display. For presentation purposes, the templates include only three rows or domains, but it is important to include as many are needed to address the intent. In addition, the cells of the first row or column (in italics) contain guidance for what to include.

Comparing qualitative and quantitative data or results for a more complete understanding through joint displays

Joint display can be used to facilitate the comparison of qualitative and quantitative results. This structure for a joint display is applicable to most any design, including common designs such as a convergent, explanatory sequential, and exploratory sequential in addition to more complex designs such as case study to conduct a case-based analysis (Creamer, 2021). Table 1 provides a template for a side-by-side joint display that juxtaposes qualitative with quantitative results along with meta-inferences developed through integrative analysis. The process of developing this joint display also constitutes integrative analysis and has occasionally been termed *joint display analysis* (Fetters and Guetterman, 2021). To facilitate a comparison of qualitative and quantitative results, the joint display is organized by domain. The domain could be a concept from a theoretical model, a qualitatively derived domain, or a quantitative construct or variable. The idea of this template is to link related qualitative and quantitative results and examine those results one domain at a time to develop meta-inferences. The template provides a framework for conducting that analysis. The cells of the joint display could contain a summary of related qualitative, quantitative, and mixed methods (i.e., meta-inferences) results. Sometimes, cells also include illustrative quotes, statistics, images, or graphs such as bar charts, column graphs, boxplots, or scatterplots (Guetterman et al., 2021). Through a side-by-side joint display, the researcher has a framework for integration, but also has a way to communicate the comparison of results and meta-inferences to the reader.

An excellent example of a side-by-side joint display is the study by Haynes Brown in which she displayed quantitative results next to classroom observation data. The design was an explanatory sequential case study that began with questionnaires and lead to follow-up qualitative observations to better explain results. By looking across, they attempted to “determine whether the case study findings for each teacher confirmed their initial case classification based on the self-report data from the questionnaire” (Haynes-Brown and Fetters, 2021, p. 11). Another example is Howell Smith et al.’s (2019) joint display that shows the iterative development of a grounded theory model of interest in engineering PhDs. The joint display is oriented vertically rather than side-by-side so the reader can easily compare refinement of the visual model through qualitative and quantitative phases of research.

Examining patterns of qualitative and quantitative results through joint displays

A joint display can also be used to examine patterns such interrelationships of the qualitative and quantitative results by examining themes-by-statistics or statistics-by-themes. This type of joint display looks like a crosstabulation or contingency table. One option to is to examine statistics for themes to determine whether any patterns are present. Table 2 provides a template for this joint display in which columns are themes and quantitative constructs or variables are rows. For example, researchers might select a theme, and look at a statistical profile for the individuals for whom that theme was present. This method works best when themes are not

Table 1 Side-by-side joint display template.

<i>Domain</i>	<i>Qualitative results</i>	<i>Quantitative results</i>	<i>Meta-inferences</i>
Domain 1	<i>Summary of themes/subthemes, perhaps illustrative quotes</i>	<i>Summary of results, perhaps statistical results such as coefficients, confidence intervals, p values, effect sizes</i>	<i>Summarize meta-inference, perhaps indicate convergent or divergence of qualitative and quantitative</i>
Domain 2			
Domain 3			

Table 2 Themes-by-statistics joint display template.

	<i>Theme 1 or type 1</i>	<i>Theme 2 or type 3</i>	<i>Theme 3 or type 3</i>	<i>Meta-inferences</i>
Construct 1 or variable 1	<i>Summary of theme 1 related to construct 1, perhaps illustrative quotes</i>	<i>Summary of theme 2 related to construct 1, perhaps illustrative quotes</i>	<i>Summary of theme 3 related to construct 1, perhaps illustrative quotes</i>	<i>Meta-inference 1: Summary of meta-inference across themes or types</i>
Construct 2 or variable 2				<i>Meta-inference 2</i>
Construct 3 or variable 3				<i>Meta-inference 3</i>
	<i>Meta-inference A: Summary of meta-inference across constructs or variables</i>	<i>Meta-inference B</i>	<i>Meta-inference C</i>	

universally present for all participants or sites. The final row and final column of this template are to include meta-inferences looking across themes or across variables. An extension of this approach is to qualitatively develop a typology of individuals and to examine statistical differences or similarities among the types. Figure could alternatively include a type for each column or be transposed with variables as columns and themes as rows.

As an example of this type of joint display, researchers examined uncertainty during critical incidents for individuals in medical residency training (Hamui-Sutton et al., 2015). They developed a qualitatively typology of five types of uncertainty (Technical, Communicational, Conceptual, Systemic, Ethical) and examined quantitative variables for each. Although they did not use the term, they essentially developed a joint display as a matrix with types of uncertainty as rows and as columns for the mean level of perceived uncertainty and mean level of perceived stress measured on a five-point scale.

Connecting to identify samples through joint displays

A joint display can be used to describe the systematic selection of samples based on the results of one phase of research. This structure can apply to any sequential type of mixed methods design in which one phase informs sampling decisions for the next phase. Table 3 presents a sampling joint display template that depicts the relationship between the results of one phase and the sample of the next (McCrudden et al., 2021). The joint display is organized by domain, which could alternatively be a concept from a theoretical model, a variable, or a key result. The next column is quantitative results, if phase came first, followed by a column to describe the qualitative sample. For instance, this column could be used to describe demographic characteristics to consider or the plan to sample those who improved in an educational intervention and those who did not. The final column might be used to indicate a rationale for the sampling decision—strengthening the tight connection while integrating from the quantitative phase to the qualitative phase. For representing how qualitative results informed a subsequent quantitative sample, having the qualitative column to the left and quantitative to the right will better reflect the flow of procedures in the design.

As an example of this joint display, McCrudden and McTigue (2019) included a joint display that indicated how they used quantitative data to sort individuals into two groups for subsequent purposeful sampling. The focus of the explanatory sequential mixed methods study was to examine bias in beliefs about climate change among high school students. They calculated a bias score to identify students with more-objective versus less-objective reasoning. The joint display sorted these two groups and provided their rating of arguments for different types of climate change from which they purposefully sampled participants for follow-up interviews to better understand the quantitative ratings (McCrudden and McTigue, 2019).

Building data collection instruments through joint displays

A joint display is also used to depict the systematic development of data collection instruments from a phase of research. For example, from quantitative results, a joint display could identify specific questions in a semi-structured interview to explain results. An innovation on this type of display developed by McCrudden and McTigue (2019) includes a rationale for the question as the

Table 3 Sampling joint display template.

<i>Domain</i>	<i>Quantitative results</i>	<i>Qualitative sample</i>	<i>Rationale for sample</i>
Domain 1	<i>Statistical summary for domain 1, perhaps coefficients, confidence interval, p values, or effect sizes</i>	<i>Description of sampling for domain 1, such as purposive sampling criteria, sample size</i>	<i>Reason for sampling decision</i>
Domain 2			
Domain 3			

final column. Alternatively, a joint display could depict how a survey was developed or adapted based on results from an initial qualitative exploratory phase.

Tables 4 and 5, respectively, provided templates for showing how quantitative results inform interview questions and how qualitative results can inform an instrument. **Table 4** provides a potential structure for an Interview Questions joint display to show how quantitative results informed qualitative interview questions. This joint display is also organized by domain, which could alternatively be a construct from a theoretical model, a variable, an aim, a research question, or another relevant field. The template begins with quantitative results, which come first temporally followed by a column for the relevant interview question. The quantitative results and interview questions do not have to be a one-to-one relationship. For example, a particular result might have no related questions or multiple follow-up interview questions. The point of this joint display is to systematically write interview questions (or focus group questions) based on quantitative results to help address research questions. As previously noted, the final column provides a rationale for the question, a recommendation by [McCrudden and McTigue \(2019\)](#). They provided an exemplar of this type of joint display from their study of beliefs about climate change in which they linked specific follow-up questions based on students' responses to a rating scale along with what they hoped to elicit through the interview question.

Table 5, on the other hand, presents a template for linking qualitative results to quantitative items being developed based on those results. Again, following the sequential order of the research procedures, this joint display has qualitative results in the first two columns followed by the quantitative items developed in the next column. The link between codes and items does not have to be one-to-one and should be based on the intent of the instrument developed. Researchers used this type of joint display to link constructs and subconstructs from a grounded theory model and quotes from participants to scale items to measure interest in an engineering PhD ([Howell Smith et al., 2019](#)). The joint display provides an example of including quotes that then inform item writing.

Table 6 provides a variation when the intent is to adapt an existing instrument or instruments. This type of joint display systematically indicates how qualitative results inform adaptations. For example, if the desire is to use mixed methods to adapt an instrument to ensure cultural or contextual relevance, this joint display provides a method to review existing items and show what items are revised, added, or removed. The final column includes a rationale for the specific adaptations made.

Explaining variation in outcomes through joint displays

A joint display can be used to explain variation in outcomes. The template in **Table 7** is similar to the statistics-by-themes joint display but transposed in this template. Developing this type of joint display facilitates the analysis of patterns for a theme across levels of a variable or patterns for levels of a variable across themes. The cells might include a summary of the result for a particular theme and level of the variable. The final column and row of the template includes a space for meta-inferences. This type of joint display facilitated analysis in a study examining differential effects of an intervention to improve communication skills using practice-oriented training with virtual humans ([Guetterman et al., 2019](#)). The joint display allowed us to examine questions such as, what did we learn about the theme of motivation across low, middle, and high performers in the intervention and what is a thematic profile of a high performer? The published joint display in [Guetterman et al. \(2019\)](#) did not include meta-inferences, but developing the joint display facilitated our analysis and identification of meta-inferences that are included in the prose instead.

Table 4 Interview questions joint display template.

Domain	Quantitative result	Qualitative interview question	Rationale for question
Domain 1	Statistical summary for domain 1, perhaps coefficients, confidence interval, p values, or effect sizes	List specific interview questions or focus group questions for domain 1	Reason for adding particular question—what will the question elicit to help explain quantitative results
Domain 2			
Domain 3			

Table 5 Instrument development joint display template.

Theme or category	Qualitative code and illustrative quote	Quantitative item
Theme 1/Category 1	Specific codes or subthemes for theme 1/category 1 and perhaps illustrative quotes	List specific quantitative items for theme 1/category 1

Table 8 Matching integration intents to research questions to address through joint displays.

<i>Intent</i>	<i>Research question</i>
Comparing qualitative and quantitative results	• How do qualitative and quantitative results compare?
Relating qualitative and quantitative results	• What patterns emerge examining statistics by themes or themes-by-statistics?
Connecting to identify samples	• What sample will best help to explain or further elucidate quantitative results?
Building data collection instruments	• How should an instrument be developed or adapted based on qualitative results gathered to ensure contextual relevance?
	• What interview questions will help to explain or understand quantitative results?
Explaining variation in outcomes	• What do qualitative results explain about quantitative results?
	• What distinguishes higher versus lower performers?
	• How does it add to understanding

Summary of different intents of joint displays

Common intents of joint displays are comparing results, relating qualitative and quantitative results, connecting to identify samples, building data collection instruments, explaining variation in outcomes. This lists only represents five common intents and is not intended to be all-inclusive. While much has been focused on using a joint display as a presentation mechanism, researchers have found the process of developing a joint display to be useful as a mixed methods integration method (Fetters and Guetterman, 2021). I recommend thinking about the intent of the joint display—what do you hope to do and what do you want to communicate. Ideally, the joint display is matched to aims or research questions of the study. To think through options, Table 8 summarizes the common intents of joint displays and suggests potential mixed methods research questions that could be addressed.

Summary

This chapter reflects a contemporary trend in thinking about joint displays as more than just a way to present mixed methods results by advocating for the use of joint displays as an integration method in mixed methods educational research. Linking joint displays to specific intents further uncouples joint displays from design typologies. While I do not believe that a mixed methods study must

include a joint display, they provide one concrete method for integrating. Certainly, other methods of integration are valuable and valid.

Before closing, I will discuss several questions that I often receive about joint displays. First, can I include more than one joint display? Yes, many articles include more than one joint display, subject to space guidelines of journals. In addition, mixed methods dissertations often include more than one joint display. For example, a joint display might be included that links qualitative and quantitative data collection question in addition to a joint display that presents results side-by-side or relates statistics-by-themes. Moreover, researchers sometimes need to split side-by-side or statistics-by-themes joint display into multiple displays when there are many domains of interest. A second common question is: do I need to have qualitative and quantitative data in the joint display? In my opinion, both qualitative and quantitative research needs to be represented in the joint display. What is represented could be data, results, or methods (e.g., sampling decisions), but both qualitative and quantitative aspects need to be included. A third common question is: What if I do not have related quantitative (or qualitative) data to link to the other type? This issue is more difficult to overcome. However, it may be possible to present results side-by-side along with meta-inferences if the qualitative and quantitative samples are comparable. Regardless, the issue should be acknowledged as a limitation. Fourth and finally, a common question is: do meta-inferences need to be in the joint display? For some joint displays (e.g., connecting results to sampling decisions), the goal was not to identify meta-inferences, but to generate new samples or data collection instruments. When the goal is to develop meta-inferences, their inclusion is ideal, but could make the joint display too dense. If it is not possible to include meta-inferences in the joint display, it is imperative to include these insights in the text.

In conclusion, the use of joint displays has increased dramatically in the past 5–7 years. Recent joint display innovations include the use of figures, images, graphs, or other graphics (Bustamante, 2017; Guetterman et al., 2021). I recommend researchers use these templates and others only as a starting point to develop new and innovative joint displays. Future methodological scholarship should focus on additional innovations and the insight that can be gleaned from using joint displays as an integration and analysis method. Software can be extremely useful for integration and developing joint displays (Kuckartz and Rädiker, 2022). As new features are added, researchers will have more tools for creating innovative joint displays.

Visual displays in mixed methods research: integration of methods

Researchers who use mixed methods regularly include visual displays in their research articles. A visual display is a graphic representation of information (Schraw et al., 2013). Visual displays can be used to show descriptive statistics from a questionnaire, inferential statistics from an experiment, themes from qualitative interviews, and the integration of quantitative and qualitative findings to generate insights beyond a single set of data. In each of these instances, the visual display is used to show the findings from a study after the data have been analyzed. Displaying the findings from an inquiry is an effective way of communicating this information to readers. That said, researchers who conduct mixed methods research can include visual displays for several purposes such as providing an overview of a study's research process, demonstrating integration through methods, and integrating the findings from the quantitative and qualitative strands to draw new insights (Guetterman et al., 2015a, 2015b; Ivankova et al., 2006; Plano Clark and Sanders, 2015). This article provides an overview of guidelines for the design of visual displays in mixed methods research studies for different purposes. I present ideas for using visual displays (1) to show the relationship between research questions and data collection methods, (2) to communicate a mixed methods study design procedure, (3) to demonstrate integration of methods, and (4) to demonstrate integration of findings.

Visual displays and communicating the relationship between research questions and data collection methods

There are numerous mixing purposes for conducting mixed methods research (Greene et al., 1989; Newman et al., 2003). Mixed methods research involves integrating quantitative and qualitative strands in a study (Teddle and Tashakkori, 2009). A strand is "a component of a mixed methods study that encompasses the basic process of conducting quantitative or qualitative research: posing a question, collecting and analyzing data, and interpreting results" (Plano Clark and Ivankova, 2016, p. 119). Researchers use research questions to focus a study's purpose on specific statements that can be addressed empirically. In mixed methods studies, researchers can pose three main types of questions: quantitative, qualitative, and mixed methods research questions (Creswell and Plano Clark, 2018). Researchers can show an overarching mixed methods purpose and pose quantitative questions for the quantitative strand and qualitative questions for the qualitative strand. Or they can pose mixed methods research questions that signal the integration of the two strands. A discussion about the framing of research questions is beyond the scope of this article (please see Creswell and Plano Clark, 2018 for a discussion about the framing of research questions in a mixed methods study). The point being raised here is that researchers often pose multiple research questions in a mixed methods

Table 1 The relationship between research questions and data collection methods.

Research questions	Data collection methods
How do students act when they do not understand?	<i>Video recorded observations:</i> 1-hr habituation observation followed by five 1-hr observations of each class. <i>Running records:</i> For each observation, the first author took a running record of classroom events while the teacher introduced and concluded the lesson. <i>Participant observation:</i> The first author roved the class and spoke with students as they attempted practice questions. <i>Work samples:</i> Collect and photocopy students' work during lessons to determine who had struggled with the math they were learning. <i>Semi-structured teacher interviews:</i> 1-hr interview with each teacher to discuss focus students' behavior.
What is the tacit reasoning that explains students' particular patterns of help-seeking?	<i>Stimulated recall student interviews:</i> Students described aspects of their help-seeking behavior that were not directly observed (e.g., attending remedial lessons). <i>Stimulated recall interviews:</i> 30-min interviews in which students ($N = 18$) received verbal descriptions of their class behavior and were asked what they were thinking and feeling at those times.
What are the consequences of students' help-seeking/avoidance for their academic outcomes?	<i>Achievement data:</i> Collect math achievement data for the school year for all students ($N = 18$) who were interviewed. <i>Work samples:</i> Photocopy all student workbooks at the completion of each observation.

Note: Modified from Peeters et al. (2020, p. 537).

inquiry and different data collection methods are used to address these research questions. As such, both readers and the researchers themselves (when in the planning stages of a study) benefit from seeing the relationship between research questions and data collection methods.

Data collection methods are the specific means used to gather evidence to address research questions. In a mixed methods study, it is common for there to be more than one research question and more than one data collection method. When researchers are planning a study, mapping the relationship between research questions and data collection methods helps readers evaluate the extent to which the research questions and data collection methods are aligned. That is, whether the methods are appropriate for addressing the questions. For the reader, research questions and data collection methods are likely to be spread across multiple pages of an article, making it more difficult to see how the different methods will be used to address the research questions. Thus, centralizing the research questions and data collection methods in a visual display is beneficial to the researchers and the readers alike.

The visual display in **Table 1** provides an illustrative example based on Peeters et al. (2020). The research questions are provided in the left-hand column, and the adjoining data collection methods are provided in the right-hand column. Lines are included to make it easier to see how each specific method is aligned with the respective research question. Notice how the researchers provide concise descriptions of the data collection methods. They include key information in the descriptions so that readers can understand and potentially envision the enactment of each method, but they do not provide too much detail. They used the text of the article to provide more detailed descriptions of the specific methods. Thus, the description in the visual display is meant to provide a brief description of the data collection methods, not to replace the detailed description in the text of the article.

Visual displays and communicating a mixed methods study design procedure

Visual displays can play a key role in providing an overview of a study. A display can succinctly summarize the study design procedure in one place and illustrate the adage that "a picture is worth a thousand words". A mixed methods study includes two or more research strands. It can be easier for readers to comprehend the strands of a study by seeing the study design procedure. Mixed methods researchers emphasize the value of using a visual display to communicate the design procedures of a study (Creswell et al., 2003; Creswell and Guetterman, 2019; Morse 1991; Tashakkori and Teddlie 1998). Based on Morse's (1991) notation system and recommendations from mixed methods researchers (Creswell et al., 2003; Creswell and Guetterman, 2019; Tashakkori and Teddlie 1998), Ivankova et al. (2006) developed 10 guidelines for creating a visual display of a mixed methods study design procedure (see **Table 2**). Next, I will describe each of these guidelines in more detail and provide examples to illustrate them.

Guideline 1: generate a title for the visual display

This guideline signals to the reader what is being shown in the display. Displays can be used to for different purposes. Thus, signaling that the display shows the design procedures is a straightforward and efficient way of helping readers know the purpose of the display. To facilitate comprehension, it is beneficial to signal not only that the display shows the procedures, but also the type

Table 2 Guidelines for creating a visual display of a mixed methods study design procedure.

1. Generate a title for the visual display.
2. Use either a horizontal or vertical layout for the visual display.
3. Draw boxes for quantitative and qualitative stages of data collection, data analysis, and interpretation of the study results.
4. Use capitalized or lowercase letters to designate priority of quantitative and qualitative data collection and analysis.
5. Use single-headed arrows to show the flow of procedures in the design.
6. Specify procedures for each quantitative and qualitative data collection and analysis stage.
7. Specify expected products or outcomes of each quantitative and qualitative data collection and analysis procedure.
8. Use concise language to describe procedures and products.
9. Make your visual display simple.
10. Size your visual display to a one-page limit.

Note: Modified from Ivankova et al. (2006, p. 12).

Phase	Procedure	Product
 QUAN Data Collection	-Cross-sectional student questionnaires ($n = 72$)	-Numeric data
 QUAN Data Analysis	-Data screening -Mixed-model ANOVA -SPSS software v. 23	-Descriptive and inferential statistics
 Case Selection & Instrument Development	-Rank-order students based on belief bias -Use purposeful sampling to identify students with least and most belief bias -Develop interview questions	-Low belief bias ($n = 4$) and high belief bias cases ($n = 4$) -Interview protocol
 QUAL Data Collection	-Individual face-to-face semi-structured interviews with 8 participants	-Text data (interview transcripts)
 QUAL Data Analysis	-Coding and thematic analysis -Within-group and across-group thematic analysis	-Codes & themes -Similar and different themes
 Integration of the QUAN & QUAL Findings	-Interpret and explain the quantitative & qualitative findings	-Discussion and implications -Evidence of confirmation and expansion of quantitative findings

Fig. 1 Example vertical visual display of the Sequential Quantitative → Qualitative Mixed Methods Study Design Procedure described in McCrudden and Barnes (2016).

of design being used in the study. This gives the reader a frame of reference for understanding how the various parts of the study fit together. For instance, if the study uses a sequential Quantitative → Qualitative design, use a title such as, “Visual Display of the Sequential Quantitative → Qualitative Mixed Methods Study Design Procedure”, then the reader can anticipate that the display will first show a quantitative strand followed by a qualitative strand. Fig. 1 is an example of a visual display that shows the study design procedure from McCrudden and Barnes (2016).

Guideline 2: use either a horizontal or vertical layout for the visual display

The decision to use either a horizontal or vertical layout is influenced by the complexity of the study design and space available. One suggestion is to create a display with a horizontal layout and another display with a vertical layout and decide whether one layout more effectively communicates the study design procedures.

A sequence is a type of visual display that affords temporal inferences through spatial organization, commonly with other conventions such as arrows, to signal earlier and later steps/events (McCrudden and Rapp, 2017; McCrudden and Van Meter, 2021). A study's design procedure unfolds over time; thus, a sequence is an optimal visual display for conveying a study's design. Consider Fig. 1. As can be seen in the column labeled "phase", the steps taken are provided in boxes and ovals that are connected by arrows to show the temporal sequence of the study design procedures.

Further, in many instances, a sequence can be extended into a matrix. A matrix is a type of visual display that affords relational inferences through spatial contiguity (McCrudden and Rapp, 2017; McCrudden and Van Meter, 2021). The organization of the overall visual display affects the layout of the matrix. With a vertical display, the sequence can be placed in the left column of the display and flows from top to bottom (see Fig. 1). The middle column provides the procedures, the right column provides the products, and below each of those column headings are the details about the respective topics. With a horizontal display, the sequence is placed across the top row of the visual display and flows from left to right as can be seen in Fig. 2, which includes the same information as Fig. 1 but with a horizontal layout. Below the sequence are the next two rows labeled procedures and products, and the details about each are provided in the cells of the display.

The layout of the visual display is highly dependent on the study design. The examples in Figs. 1 and 2 are for a sequential Quantitative → Qualitative design. A visual display of the study design procedures for a concurrent Quantitative + qualitative design will have a different layout. For instance, Fig. 3 is an adapted visual display from White et al. (2019), who used a concurrent Quantitative + qualitative design. The examples shown here illustrate have one quantitative strand and one qualitative strand. It is important to keep in mind that designs with more strands may have different formats.

Guideline 3: draw boxes for the various quantitative and qualitative stages

The third guideline is to use boxes for the components of the quantitative and qualitative strands (e.g., data collection and data analysis), and ovals for points of interface between the strands. For instance, in Fig. 1, "QUAN Data Collection" appears in a box, whereas "Case Selection and Instrument Development" appears in an oval. Points of interface refer to specific points in the study design procedure that involve integration between strands, such as through purposeful sampling (Morse and Niehaus, 2009). In the next section, examples of integration between methods for the different strands will be provided. The overall visual display of the study design procedure can signal these points of integration and provide the reader with a zoom out view of the procedure, whereas the detailed displays can provide a zoom in view of more specific aspects of the procedure. There is nothing magical about using boxes or ovals but following some sort of consistent conventions makes interpretation of visual displays more user-friendly.

Guideline 4: use letter case to designate priority

The fourth guideline is to use capitalized or lowercase letters to designate the priority of quantitative and qualitative data collection and analysis. Priority refers to "the relative importance of the quantitative and qualitative methods for answering a mixed methods study's research questions" (Plano Clark and Ivankova, 2016, p. 33). The priority of the methods in a study is signaled with

Fig. 2 Example horizontal visual display of the Sequential Quantitative → Qualitative Mixed Methods Study Design Procedure described in McCrudden and Barnes (2016).

Fig. 3 Example visual display of concurrent Quantitative + Qualitative Study Design Procedure modified from White et al. (2019, p. 59).

uppercase and lowercase letters (Morse, 1991). When one or more of the methods are given greater priority, uppercase letters are used (i.e., QUAN, QUAL). When one or more methods are secondary, lowercase letters are used (i.e., quan, qual). In Fig. 1, the use of uppercase letters for both strands signals that both the quantitative and qualitative strands are given priority, whereas the use of uppercase and lowercase letters in Fig. 3 signals that the quantitative strand is given priority over the qualitative strand.

Guideline 5: use arrows to show the flow

Single-headed arrows can be used to show the flow or sequence of procedures in the design. Whether the visual display is vertical (Fig. 1) or horizontal (Figs. 2 and 3), the use of single-headed arrows signals the temporal sequence of the study design procedures. This helps the reader understand the study's flow and how the earlier and later steps/events are interrelated. In Figs. 1 and 2, the arrows signal the sequential flow of the entire study. In Fig. 3, the arrows signal (a) the sequential flow of each strand, (b) the concurrent flow of each strand, and (c) the integration of the two strands at the end.

Guideline 6: specify procedures for data collection and analysis

The sixth guideline is to specify the procedures for the quantitative and qualitative data collection and analysis stages. In a mixed methods research study, researchers use several procedures to collect the data and several approaches to analyze the data. To complicate matters, the text description of data collection and analysis for different strands may be described across disparate pages of the article. Summarizing the procedures for data collection and analysis for each strand of the study in a visual display provides the reader with a succinct summary of these steps. Specifying the procedures of data collection and analysis go hand-in-hand with expected products or outcomes. In the next section, I will briefly describe expected products and then provide an example of how procedures and products can be presented in a visual display.

Guideline 7: specify expected products or outcomes

The seventh guideline is to specify expected products or outcomes of each quantitative and qualitative data collection and analysis procedure. The sixth guideline specifies how data will be obtained and the analytic approaches to be used. The seventh guideline specifies the product of each data collection procedure and the product of each data analytic approach. In the quantitative strand, the product of data collection will be data from structured data-collection instruments that be in the form of variables, and the product of data analysis will commonly be descriptive and/or inferential statistics. In the qualitative strand, the product of data collection includes, for example, interviews, observations, and field notes, and the product of data analysis can include words, categories, themes, and images.

To illustrate the procedures and products for data collection and analysis, consider [Fig. 1](#). In the quantitative phase, data collection in the quantitative phase involved the use of a cross-sectional survey of 72 participants (procedure column) and resulted in numeric data (product column). Data analysis in the quantitative phase involved data screening, a brief description of the specific data analysis technique used to analyze the data (mixed model ANOVA), and the software used to analyze the data (SPSS software volume 23). The point of interface between the quantitative and qualitative strands involved case selection and instrument development. The procedures included a rank-ordering of participants based on their quantitative responses, which was used to develop criteria to purposefully sample participants for the follow-up qualitative strand (case selection). This led to the selection of eight participants for follow-up interviews. Further, quantitative data were reviewed and used to develop interview questions, which were used to create the interview protocol (instrument development). The procedure and product for the qualitative strand, their integration, and their respective procedures and products can be seen in [Fig. 1](#). Thus, the including the phase, procedure, and product columns in a visual display can provide readers a succinct overview of your mixed methods study design.

Guideline 8: use concise language

The eighth guideline is to use concise language for describing procedures and products. Readers will better understand a visual display if extraneous or unnecessary words are not included ([Mayer and Fiorella, 2014](#)). When too much information is provided, a display can become too complicated or confusing. In [Fig. 1](#), next to the oval for “Case Selection & Instrument Development”, concise language is used to describe the purposeful sampling procedure and for the development of the interview protocol. These study features can be described elsewhere in greater detail. Thus, eliminating unnecessary words helps readers focus on the important information needed to understand the study design procedures.

Guideline 9: make your visual display simple

As indicated in the eighth guideline, too much information in a display, not following general conventions, or general lack of clarity can defeat the purpose of the visual display, which is to provide a clear and concise overview of the study design procedure. For designs with two strands, it is more straightforward to develop a visual display. However, not all designs consist of only two strands. If there are more than two strands in your study is the case, you should consider drafting several different displays or using different layouts and deciding which one best addresses your purposes. Further, consider asking a co-author or colleague to review and interpret this display and use this feedback to decide whether and what changes might be needed.

Guideline 10: keep you display to one page

The 10th and final guideline is to limit your visual display to one page or less. You do not need to include every detail of the study in one visual display. You can show more detailed aspects of the study in a separate visual display. For instance, in a study design procedure, you may briefly describe the purposeful sampling criteria, and then in a separate visual display or in text you could provide a more detailed description of the purposeful sampling procedure and a description of the specific participants.

Visual displays and integration of methods

Researchers can integrate the data collection and data analysis strands of a mixed methods study in several ways. [Fetters et al. \(2013\)](#) identified four ways (connecting, building, merging, & embedding) in which researchers can link quantitative and qualitative data collection and analysis in a mixed methods study. Importantly, each of these approaches can be shown with a visual display.

Connecting

The first approach to integration through methods involves linking one database to the other through sampling (connecting). For instance, suppose researchers collect and analyze quantitative data from an experiment and want to gain a better understanding of some quantitative findings with qualitative interviews. The researchers could use the quantitative findings to inform the sampling frame for the qualitative interviews. For instance, in [McCrudden and Barnes \(2016\)](#), high school students indicated their beliefs about whether humans affect the climate and then rated equally compelling strong arguments for and against human influence on climate and equally compelling weak arguments. Their belief ratings were used to determine whether the arguments were consistent or inconsistent with their beliefs. They used these data to compute bias scores for each participant, defined as the difference between summed ratings for the belief-consistent and belief-inconsistent arguments (a low score would indicate low bias as ratings would be similar independently of whether the argument was consistent or inconsistent with the student’s beliefs). Based on these scores, they identified a subsample of students to participate in qualitative interviews and provided a visual display to describe and contrast the two distinct subgroups (see [Table 3](#)).

Table 3 Participant selection display using ratings for belief-consistent and belief-inconsistent arguments by strength.

		<i>More-objective group (n = 8)</i>			<i>Less-objective group (n = 8)</i>		
		<i>Belief-consistent arguments</i>	<i>Belief-inconsistent arguments</i>	<i>Difference score</i>	<i>Belief-consistent arguments</i>	<i>Belief-inconsistent arguments</i>	<i>Difference score</i>
		<i>M (SE)</i>	<i>M (SE)</i>		<i>M (SE)</i>	<i>M (SE)</i>	
Argument strength	Strong	6.25 (0.60)	5.69 (0.53)	0.56	6.61 (0.82)	3.06 (0.88)	3.55
	Weak	3.44 (0.82)	3.56 (0.82)	-0.12	5.33 (0.61)	2.39 (0.74)	2.94

Modified from McCrudden and Barnes (2016, p. 285).

As seen in **Table 3**, the top rows provide labels for each of the subgroups (more-objective and less-objective groups), their average ratings for belief-consistent and belief-inconsistent arguments for the strong and weak arguments, and their difference scores. The table shows differences between the two groups and provides a rationale or justification for their inclusion in the follow-up qualitative strand of the study. For instance, the difference scores for the strong arguments for the students in the more-objective group are much lower than the difference scores for the strong arguments from the students in the less-objective group (0.56 vs. 3.55), which suggests that students in the less-objective group use more biased reasoning. The same pattern holds true for the weak arguments (-0.12 vs. 2.94). Thus, the researchers could use these data to purposefully sample participants for the follow-up qualitative interviews to gain a deeper understanding of the different reasoning patterns students on both groups used to evaluate the arguments. The visual display gives the researcher a basis for identifying participants for the interviews and it makes the participant selection procedure clearer to the reader.

Building

The second approach involves using one database to inform the data collection of the other database (building). In other words, data from a previous strand is used to inform data collection for a subsequent strand. For instance, suppose researchers collect and analyze quantitative survey data and want to gain a better understanding of some quantitative finding with qualitative interviews. The researchers could use the quantitative findings to inform the development of the qualitative interview protocol. [Cunningham-Erves et al. \(2018\)](#) used a sequential Quantitative → Qualitative design to investigate Black mother's intention to vaccinate daughters against Human Papillomavirus (HPV) given the cervical cancer disparity between Black and non-Hispanic White women. In the quantitative strand, Black mothers of daughters ($n = 237$) completed a survey and nine of these women participated in follow-up qualitative interviews that were based on the survey results (see **Table 4**). Based on the quantitative findings, the researchers identified relevant constructs from the survey and provided sample survey items along with corresponding items from the qualitative interview to gain a deeper understanding of the constructs.

This approach can also be used in a sequential Qualitative → Quantitative study design. For instance, suppose researchers collect and analyze qualitative focus-group interview data and want to test the generalizability of the themes identified from the qualitative data analysis. The researchers could use the themes from the qualitative interviews to develop items for a quantitative survey, which could be shown in a visual display. [Kumar et al. \(2019\)](#) used a sequential Qualitative → Quantitative study design to investigate features of culturally responsive learning environments with students from across 12 middle schools in two nearby school districts. In the qualitative strand, they conducted 57 focus-group interviews with students ($n = 333$) from different cultural backgrounds about their interactions and experiences in their schools. They used the themes generated from the qualitative data analysis to develop a quantitative questionnaire and then tested its validity with students ($n = 2894$) who had similar backgrounds as students from the qualitative strand. The researchers linked the themes from the qualitative strand to the factors and survey items in the quantitative strand as shown in **Table 5**, which includes an example excerpt from one of their theme/factor pairs. The left-hand column provides an excerpt from the qualitative strand; specifically, one of the themes identified in the data analysis and illustrative quotes to substantiate the theme. The right-hand column provides an excerpt from the quantitative strand; specifically, one of the factors and the corresponding survey items. Including the qualitative and quantitative strands in the visual display enables readers to understand and trace the relationship between the two strands.

Merging

The third approach involves bringing together the databases together for analysis (merging). With this approach, researchers develop/identify quantitative and qualitative measures around a common topic before collecting data. After collecting data, each data set is analyzed independently. Next, the researcher brings together the findings from each strand together to find convergence, divergence, or extension. For instance, when using a concurrent design, researchers might collect data with a quantitative survey and a qualitative interview. Elements of the survey and interview protocol can be aligned to show how they are linked before data

Table 4 Visual display of developing interview questions from relevant survey results.

Table used by [Cunningham-Erves et al. \(2018\)](#).

Reprinted from Cunningham-Erves, Forbes, Ivankova, Mayo-Gamble, Kelly-Taylor, and Deakings, Black mother's intention to vaccinate daughters against HPV: A mixed methods approach to identify opportunities for targeted communication. *Gynecologic Oncology*, 149(3), 506–12 (2018), with permission from Elsevier.

<i>Applied theory</i>	<i>Construct</i>	<i>Sample survey (quan) item</i>	<i>Sample interview (qual) protocol item</i>
TRA	Distal variable (knowledge)	Only women get HPV.	What do you know about HPV and cervical cancer?
TRA	Distal variable (personal experience)	Have you, or anyone close to you, ever had HPV, an abnormal Pap smear (pap test), genital warts, and/or cervical cancer?	What personal experiences have you had with HPV?
TRA	Subjective norms	If your doctor recommends the HPV vaccine, how likely is it that your child will get it?	How have other people you know influenced your decision to vaccinate/not vaccinate your daughter against HPV?
TRA	Distal variable (culture)	I often think about how my actions today will affect my health when I am older.	What role, if any, has your cultural experience played in your decision to vaccinate/not vaccinate your daughter against HPV?
TRA	Perceived barriers	I don't trust the information on the HPV vaccine provided by the physician.	What challenges, if any did you/do you face when deciding to vaccinate/not vaccinate your daughter now?
TRA	Perceived benefits	The HPV vaccine is a good way to protect my daughter's health.	In your opinion, what benefits, if any, would there be to vaccinate/not vaccinate your daughter against HPV?

Note: TRA stands for Theory of Reasoned Action.

Table 5 Visual display for building by linking databases in sequential Qualitative → Quantitative study design.

<i>Qualitative strand</i>	<i>Quantitative strand</i>
Theme: Perceptions of teachers as prejudiced and culturally insensitive versus respectful and culturally responsive Quotes: • "They should talk to you with some respect that we talk to them with. Some teachers don't have any respect for you even though you wouldn't disrespect." • "We have like our own whole caste system going on that the teachers have like completely no idea about." • Female 1: "They don't say anything about it (political issues). Anytime someone tries to bring it up, it's inappropriate. It's too political. Shouldn't talk about that here. It's not for school." • Female 2: "See both sides. Don't make it that you're talking about one side and not the other. Like all the teachers ..."	Factor: Promoting cultural openness and positive intergroup relationships Survey items: 1. Listen with an open mind to what students in the different groups are saying. 2. Help students in each of the groups understand how students from the other group feel.

Modified from [Kumar et al. \(2019, p. 92\)](#).

collection (see [Table 6](#)). [Ogilvie and McCrudden \(2017\)](#) used a concurrent Quantitative + Qualitative design to investigate the social validity of a behavioral intervention for children with autism. Parents completed a quantitative questionnaire and participated in qualitative interviews to investigate their perceptions of the social validity of the behavioral intervention for their children. [Table 6](#) consists of three columns and includes an excerpt from the materials from [Ogilvie and McCrudden \(2017\)](#). The left column provides the factor or category targeted by the specific quantitative survey items (middle column) and the specific qualitative interview prompts (right column).

Table 6 Visual display for merging by linking databases for analysis in a concurrent Quantitative + Qualitative design.

Category	Quantitative survey items	Qualitative interview prompts
Understanding	- How clear is your understanding of this treatment?	- What aspects of this treatment do you understand well? - What aspects of this treatment do you not understand? - How can we make it more understandable in the future?

Modified from Ogilvie and McCrudden (2017, p. 2908).

Embedding

The fourth approach involves linking data collection and analysis at multiple points throughout a study (embedding). Embedding “is especially important in interventional advanced designs, but it can also occur in other designs” (Fetters et al., 2013, p. 2141) and it can involve different combinations of integration through methods (connecting, building, merging), although embedding can be used for a variety of mixed methods research inquiries. For an interventional advanced design, a qualitative data can be embedded at various points in the design, including before, during, and/or after the intervention (see Fig. 4). Creswell and Plano Clark (2018) provide detailed examples of different ways to use visual displays to show advanced designs.

Visual displays and integration of findings

Researchers can use visual displays to integrate the quantitative and qualitative findings of a mixed methods study. Visual displays can be used to communicate important findings from the respective quantitative and qualitative strands and to support inferences about the integration of the strands via spatial arrangement. An example is an integrated results matrix (see Table 7) based on McCrudden and Barnes (2016). This type of display facilitates comparison of the quantitative and qualitative results by organizing the results from the respective strands. In Table 7, the second column of the display (Quantitative

**Fig. 4** General visual display for embedding qualitative approaches in an interventional design. Modified from Guetterman et al. (2015a, p. 169).**Table 7** Integrated results matrix.

Group	Quantitative findings	Qualitative findings	Meta-inference
More-objective	Rated strong arguments more favorably than weak arguments, independently of belief-consistency.	Uniform application of normative evaluation criteria at a deep level.	Holding a belief did not necessarily lead to biased reasoning; rather, biased reasoning occurred when individuals applied a more critical standard of evaluation to belief-inconsistent arguments.
Less-objective	Rated belief-consistent arguments more favorably than belief-inconsistent arguments, independently of strength.	Belief-based application of normative evaluation criteria (more critical of belief-inconsistent arguments) and use of ideas that were irrelevant to the argument's validity.	

Modified from McCrudden and Barnes (2016, p. 292).

findings) shows important quantitative data and a summary for each group; the third column (Qualitative findings) provides a summary for of the qualitative themes for each group. The last column on the right provides the meta-inference, which is a conclusion a researcher generates by integrating the inferences obtained from the quantitative and qualitative strands of a mixed methods study (Teddle and Tashakkori, 2009). There are several ways to develop joint displays to convey findings from a mixed methods research study. Guetterman et al. (2015a, p. 158) list nine guidelines for creating joint displays and Guetterman et al. (2015b) provide illustrative examples of joint displays that have appeared in journals that publish state-of-the-art mixed methods research.

Conclusion

Visual displays can give readers a conceptual scaffold for understanding information (McCrudden et al., 2015; McCrudden and Rapp, 2017). Researchers can use visual displays in mixed methods research in ways that effectively communicate key aspects of a study. This review highlighted four purposes of visual displays in mixed methods research, including to show the relationship between research questions and data collection methods, to communicate a mixed methods study design procedure, to demonstrate integration of methods, and to demonstrate integration of findings. Each of these purposes pertains to the methodological features of a mixed methods study. For instance, an effective visual display that shows a mixed methods study design procedure succinctly describes the steps taken to collect, analyze, and interpret data. However, there are other purposes that are not covered here, such as integration of paradigms. Further, the examples provided here represent a handful of different ways the visual displays can be used in mixed methods research. Other formats, such as the use of geocoding, Venn diagrams, graphs, are but a few possibilities. I hope that the examples here are useful and readers are encouraged to consider additional possibilities including different formats and purposes. In sum, considering the purposes and formats of visual displays can guide researchers to identify effective ways of communicating information and ideas about mixed methods research.

EDITORS IN CHIEF – BIOGRAPHIES

Robert J Tierney

Rob Tierney is an international educator whose passion is for developing research partnerships to address local literacy needs with educators in different countries. Rob began his career as a classroom teacher in Australia, then proceeded to work in the United States, Canada, Australia and China. He is Dean Emeritus and Professor Emeritus of Language and Literacy Education at the University of British Columbia, the former Dean and Honorary Professor of the Faculty of Education and Social Work at University of Sydney, and a Distinguished University Professor at Beijing Normal University. In the United States, he has served on the faculties of the University of Illinois, University of Arizona, The Ohio State University, Harvard University, and the University of California. Rob has written a number of books and numerous articles on literacy especially related to global issues, diversity, and literacy development. His most recent book was entitled *A History of Literacy Education: Waves of Research and Practice* published by Teachers College Press in 2021. During his tenure as an educator, he has served as the President of the International Literacy Association, President of the Literacy Research Association, an Editor for the *Reading Research Quarterly*, the President of the Association of Canadian Deans of Education/ L'Association Canadienne des Doyens et Doyennes d'éducation, as well on a number of committees and boards for professional groups and government and nongovernment

agencies. In addition, he has been involved on a range of groups on projects globally including in Africa and Asia including for UNESCO, Children's Television Workshop, and Apple Computer.

Fazal Rizvi

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia–Asia relations. He has published widely, and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge 2010) is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge 2022) has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

**Kadriye Ercikan**

Kadriye Ercikan is Vice President of Research and Measurement Sciences at the Educational Testing Service and Professor Emerita at the University of British Columbia. She is responsible for ETS's foundational and applied research and psychometric support of ETS's major testing products and contracts, and the NAEP contract for ETS. Her research focuses on validity and fairness issues and sociocultural context of assessment. Her recent research includes validation of score meaning using response processes, use of response process data for comparing groups and examining fairness and validity of interpretation, and use of scores from artificial intelligence-based automated scoring.

Ercikan is a Fellow of the International Academy of Education. Her research has resulted in 6 books, 4 special issues of refereed journals, and over 100 publications. She was awarded the AERA Division D Significant Contributions to Educational Measurement and Research Methodology recognition for another

coedited volume, *Generalizing from Educational Research: Beyond Qualitative and Quantitative*

Polarization, and received an Early Career Award from the University of British Columbia. Ercikan has been selected to serve as the NCME Book Series Editor (2021–2026).

SECTION EDITORS

Jason Beech is Associate Professor (Global Policy) at the University of Melbourne and visiting professor at Universidad de San Andrés in Buenos Aires where he holds a UNESCO Chair in Education for Sustainability and Global Citizenship. He is senior researcher of the National Council for Scientific and Technical Research of Argentina (CONICET), and Associate Editor of *Education Policy Analysis Archives*. He has been a member of the Board of Directors of the Comparative and International Education Society (2014-2016). Jason has published extensively on the globalization of knowledge and policies related to education. He has also written and is passionate about the challenges of educating for global citizenship and a sustainable future. He has taught in several universities in the Americas, Europe and Australia.

Professor Qing Gu is Director of the UCL Centre for Educational Leadership and Professor of Leadership in Education. She is the Past Chair of the *British Association of Comparative and International Education* (BAICE), Co-Editor of *Teachers and Teaching: Theory and Practice*, Associate Editor of *International Journal of Educational Development*, a member of the Research Standing Committee of the World Council of Comparative Education Societies (WCCES), and a member of the Research Evidence and Impact Panel for the Leadership College for UK Government. Professor Gu has directed and codirected many government and research council funded projects in the areas of teacher professional development, school improvement, and systemic reform and change. She has led a £1.9 m UK Economic and Social Research Council (ESRC) funded project *Schools as Enabling Spaces to Improve Learning and Health-Related Quality of Life for Primary School Children in Rural Communities in South Africa*. Some of her books have been translated into Chinese, Japanese, and Spanish.

Professor Smith is a New Zealand Maori of Te Aitanga a Hauiti, Ngati Porou, Kati MamoeNgati Apa, Ngati Kahungunu descent. He is a highly regarded and internationally recognized, Maori educationalist and scholar. He has been at the forefront of transforming Maori and Indigenous social, economic and cultural conditions through re-developing education and schooling outcomes. His work links theoretical thinking and practical applications within an ongoing cycle of transforming praxis.

Professor Smith trained as a teacher at Auckland Teachers College and taught in Auckland schools. He also lectured in Education at the Auckland College of Education. He was one of the first teachers and developers of a Kura Kaupapa Maori, an alternative, Maori philosophy and principles-based School. These Maori immersion schools have grown from a single entity in 1988 to over seventy-five publicly funded schools in 2015. His theoretical leadership in the Education Department at the University of Auckland helped inform the emergence of Maori Education as a distinct field of study across the New Zealand Tertiary Sector. This work has encouraged a wide range of academic studies focused on overthrowing persisting inequities within and as a result of education and schooling in New Zealand. His significant contribution to New Zealand education is to be seen in his work related to Kaupapa Maori as a theory of Transformative Praxis. All of these elements derive from his PhD research entitled, "The Development of Kaupapa Maori: Theory and Praxis (1997)".

Professor Smith's later academic work centered on developing theoretically informed strategies related to transforming high and disproportionate levels of Maori cultural, political, social, educational, and economic marginalization. He has been a significant scholar involved in the emergence of Tribal "universities" institutions (Wananga) and is the former foundation Chair of the Council for Te Whare Wananga O Awanuiarangi. He led the successful Treaty of Waitangi Claim and settlement for Awanuiarangi. In his former position as Pro Vice Chancellor (Maori) at the University of Auckland, he was responsible for developing significant structural change within the institution while working within the Office of the then Vice Chancellor, Dr. John Hood. Notable achievements included implementing a Maori development strategy within the University which required all Deans to be responsive in their performance results for Maori and Pacific advancement; the oversight of the Proposal and winning of a National Centre of Research Excellence (Nga Pae o te Maramatanga); the initiation of the Maori and Indigenous doctoral program aimed at creating 500 Maori PhD graduates across the country in five years; the recruitment of top Maori academic scholars into the University of Auckland; the development of Kaupapa Maori as a theory of transformative praxis and which has had national and international influence. Professor Smith also served on the University of Auckland Council for three years as the Professorial representative for Academic staff.

In 2007 Professor Smith accepted a role as the Universitas 21 Distinguished Visiting Professor in Indigenous Education hosted by the University of British Columbia (within the Faculty of Education). Although the position was initially intended for two years, the role was extended for a further three years. While situated at the University of British Columbia, Professor Smith also chaired the Educational Policy Studies Department for three years. These positions allowed engagement with many Canadian universities as well as other universities across the world.

Professor Smith has made significant contributions to the political, social, economic, and cultural advancement of Maori and indigenous communities in New Zealand and around the Pacific Rim. He has worked extensively with other Native/Indigenous/First Nation's peoples across the world, including in Canada, India, US mainland (including extensive work in Hawaii and Alaska), Norway, Taiwan, Chile, Australia, as well as with selected Micronesian and Pacific nations. He is a regular contributor to national and international forums and conferences. Professor Smith has been an authoritative voice within the critical debates on *social, cultural and economic inequality* both in New Zealand and abroad, and he maintains a strong influence in the Maori/Indigenous languages revitalization movements.

Professor Smith stepped down from the administrative position of CEO/Vice Chancellor at Te Whare Wananga o Awanuiarangi in 2015 after eight years in the role. He resumed his academic research and writing career. In 2019 he was invited to take up a special Chair – Te Toi Ihorei ki Purehuroa – A "distinguished Professorial position at large" established for him at Massey University.

Professor Smith has been recognized and honored for his international contributions, receiving an Honorary doctorate (D.Litt.) from the Okanagan University College in 2005, and an Honorary doctorate (LLD) from the University of Northern British Columbia in 2013; he was elected as a Fellow of the American Education Research Association in 2014, and was awarded a Queens Honour – a CNZM in 2014. He was given the Prime Minister's Life-time Achievement Award (2017); and received the Te Ururangi National Award for Education (Matariki Awards, 2019).

Professor Smith is married to Professor Linda Tuhiwai Smith and they have one daughter and two mokopuna (grandchildren).

Therese N. Hopfenbeck is Professor of Measurement Analytics in the Melbourne Graduate School of Education, The University of Melbourne. Before starting her position in Melbourne, she was Professor in Educational Assessment and Director of the Oxford University Centre for Educational Assessment. She is a Visiting Fellow at Kellogg College, University of Oxford, elected Vice-President of *The Association for Educational Assessment-Europe* and Lead Editor of the journal *Assessment in Education, Principle, Policy and Practice*. Dr. Hopfenbeck's research agenda focuses upon bridging research on self-regulation and classroom-based assessment and making sense of international large-scale studies in education. In collaboration with Professor Nancy Perry, University of British Columbia, she is currently leading an international network of researchers disseminating classroom-based research, funded by Social Sciences and Humanities Research Council of Canada (2020–2022). She is also currently Principal Investigator for two research projects funded by IB, on critical thinking in PYP schools internationally and evaluation of education reforms in Kent, UK (2020–2022). In 2020, she led the research on Critical Thinking in the Diploma Program in Australia, England, and Norway (<https://ibo.org/research/outcomes-research/diploma-studies/critical-thinking-skills-of-dp-students/>). Dr. Hopfenbeck was Principal Investigator for the PISA (2022) study in England, Northern Ireland, and Wales, in collaboration with Pearson UK (2018–2023). She was the Research Manager of PIRLS (2016), funded by The Department of Education, UK.gov, and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019). Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). She has advised on the implementation of formative assessment programs in India, South Africa, Norway, and the Emirates and carried out policy work for UNESCO/OECD and the Norwegian Ministry of Education Norway. Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

tion, [UK.gov](https://www.uk.gov/), and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019). Nataliya Ivankova, PhD, MPH, is Professor in the School of Health Professions at the University of Alabama at Birmingham (UAB). As an applied research methodologist working at the intersection of mixed methods, qualitative, community-based, action, and translational research, she is internationally recognized for her empirical and methodological publications. She shares her research expertise through teaching mixed methods and qualitative research courses, conducting workshops and guest lectures, mentoring doctoral students and junior faculty, and serving as key personnel on funded research projects. At UAB, she directs an online graduate certificate program in *Applications of Mixed Methods Research* and oversees the design and analytical aspects of qualitative and mixed methods studies through the Center for Health Informatics for Patient Safety and Quality. She is a founding Coeditor of the *Mixed Methods Research Series* (Sage) and serves as an Associate Editor for the *Journal of Mixed Methods Research*.

Professor Jahnke is Director of Toi Kura Centre for Maori & Indigenous Education. She was the 2019 inaugural Toi o Te Wananga Fellow. Professor Jahnke holds professional qualifications in education and is cofounder and immediate past Chair of the Indigenous Peoples of the Pacific Special Interest Group of the American Education Research Association (AERA). She currently serves on the AERA Executive Committee. She was a member of the Social & Human Sciences Sub Commission of the NZ National Commission for UNESCO, the NZ Bioethics Council, the NZ Ethics Committee on Assisted Reproduction Technology, and Chair of NZ Health Research Council Ethics Committee. She is currently Cochair of the Aotearoa Research Ethics Board and a Fulbright Scholar.

Berit Karseth, PhD, is Professor at the University of Oslo, Department of Education. Karseth's main research and publications lie in the field of education policy, reforms, and curriculum studies. She has edited four books and written several journal articles and book chapters in both Norwegian and English. Her most recent publications in English include articles published in the *Journal of Education Policy*, *Scandinavian Journal of Educational Research*, *Journal of Curriculum Studies*, and *European Educational Research Journal*. Karseth was the elected dean of the Faculty of Educational Sciences at the University of Oslo 2013–2016 and is currently in the leadership team of the research group Curriculum studies, educational leadership, and governance (CLEG) at the same institution.

Dr. Kenneth Leithwood is Emeritus Professor at OISE/University of Toronto and an honorary professor at the University College London and the University of Nottingham. His research and writing is about school leadership, educational policy, and organizational change. He has published extensively on these topics. For example, his most recent books include *Leadership Development on a Large Scale: Lessons for Long-term Success* (2018, Corwin), *How School Leaders Contribute to Student Success* (2017, Springer), and *Linking Leadership to Student Learning* (2012, Jossey Bass). Professor Leithwood is the inaugural recipient of the University of Toronto's *Impact on Public Policy* award, AERA (2011) *Outstanding Leadership Researcher Award*, the 2012 *Roald F. Campbell Lifetime Achievement Award* from the University Council for Educational Administration, and the Ontario Principals' Council *Outstanding Educator of the Year* award for 2017. He is a *Fellow of the Royal Society of Canada*. A recently published bibliometric analysis found that Dr. Leithwood was the most frequently cited, highest impact educational leadership researcher in the world.¹ Research.com's 2022 Ranking of the Top 1000 Scientists in the area of Social Sciences and Humanities ranked Dr. Leithwood 70th in the world and 7th in Canada.

Xiufeng Liu is a Professor of Science Education at State University of New York, Buffalo, and a Fellow of the American Association for the Advancement of Science (AAAS). He obtained his PhD from the University of British Columbia in 1993. Before his current position, he taught high school chemistry in China, and was a tenured faculty member at St. Francis Xavier University and University of Prince Edward Island, both in Canada. From September 2020 to August 2022, he served as a program director in the Division of Research on Learning of the National Science Foundation. Dr. Liu conducts research on measurement and evaluation of STEM education and student learning of cross-cutting concepts of matter and energy. Dr. Liu is currently a Coeditor-in-chief for the journal *Disciplinary and International Science Education Research* (Springer) and an Associate Editor for the *Journal of Research in Science Teaching*, a premier journal in science education.

Margie Maaka is a Professor of Education at the University of Hawai'i at Mānoa. Her PhD is in educational psychology. She also holds professional qualifications in education from the University of Waikato and Hamilton Teachers College. She is cofounder and current Program Chair of the Indigenous Peoples of the Pacific Special Interest Group (SIG) of the American Educational Research Association (AERA). From 2017 to 2020, she served as a member of the AERA Executive Council and Chair of the SIG Executive Committee. Before that (2014–2017), Professor Maaka served as a member of the SIG Executive Committee. She has also served as a member of the Ngā Pae o te Māramatanga Center of Research Excellence International Research Advisory Panel. Her research on community-based educational renewal saw her recognized as a national scholar with the Goodlad Institute for Educational Renewal. As Cochair of the Sovereign Councils of the Hawaiian Homelands Assembly's Committee on Education, she prepared educators and educational leaders for public schools in the Hawaiian Home Lands Trust communities. Currently, Professor Maaka is committed to the preparation of indigenous educational leaders in higher education. Her research interests include community partnerships, educational psychology/indigenous educational psychology, indigenous development and advancement, educational policy, multiliteracies, and language and cognitive development.

Diane Mayer is Professor Emerita at the University of Oxford. Her research and scholarship focus on teacher education and early career teaching, examining issues associated with the policy and practice of teachers' work and teacher education.

Daniel McCaffrey is the Associate Vice President of Psychometric Analysis and Research in the Research and Measurement Science unit of the Research and Development division at ETS. Dan's research interests include the evaluation of artificial intelligence scoring of constructed responses, developing tools and methods for causal modeling, evaluating the psychometric properties of student achievement growth measures derived from annual test scores, and methods to account for measurement error in secondary data analysis. Dan received his PhD in Statistics from North Carolina State University in 1991.

Judy Parr is Professor Emerita at the University of Auckland, Faculty of Education, where she was the founding Head of the School of Curriculum and Pedagogy. A psychologist, Dr. Parr's research program is located broadly within improvement science. Her expertise is in literacy, specifically writing and its development, encompassing instructional issues like teacher knowledge and practice and the assessment of writing. Much research has been collaborative, with colleagues and practitioners within major national projects for school improvement aimed at raising achievement in literacy and, internationally, as part of funded large-scale research projects, for example in Canada and Norway. Dr. Parr has published widely in the areas of literacy, assessment, and professional learning.

Jeong-eun Rhee is a Professor of Education, Long Island University, Post, New York. Born and raised in Seoul, Korea, she earned her bachelor's degree in Educational Psychology from Ewha Women's University. In 1992, she came to the US as an international student and received an MA in Educational Psychology from West Virginia University and a PhD in Educational Policy and Leadership from the Ohio State University. As an interdisciplinary cultural researcher and educator, her recent work focuses on developing and supporting transnational, intergenerational, and decolonial feminist knowledge projects in/through antioppressive education. She recently published *Decolonial Feminist Research: Haunting, Rememory, and Mothers*, which received an honorable mention for the 2022 Qualitative Book Award of International Congress of Qualitative Inquiry.

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge, 2010), is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge, 2022), has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

Theresa Rogers is Professor of Language and Literacy Education at the University of British Columbia. Her research interests include youth arts, media and critical literacies, adolescent literature, and teacher education in literacy. Most recently she published "Youth Activism through Critical Arts, Transmedia, and Multiliteracies" in the *Oxford Research Encyclopedia*. She is author of the book, *Youth, Critical Literacies and Civic Engagement: Arts, Media and Literacy in the lives of adolescents* (Routledge) and numerous articles in scholarly journals such as *Literacy Research: Theory, Method and Practice*, *Reading Research Quarterly*, *Pedagogies*, *Language Arts*, *Children's Literature in Education* and *Journal of Literacy Research*. See: <https://ubc.academia.edu/TheresaRogers>.

Professor Chika Sehoole is a Professor of Higher Education and the Dean of the Faculty of Education at the University of Pretoria. He obtained his PhD at the University of the Witwatersrand, Johannesburg, in December 2002. In 2003/4 he was a visiting Rockefeller postdoctoral fellow at the Centre for African Studies at the University of Illinois in Urbana Champaign. In 2005/06 he was a New Century Fulbright Fellow, again, at the same university. His research interests are in the areas of higher education policy, internationalization of higher education, higher education in Africa, and teacher education. He has served in several international research projects focusing on higher education and providing expertise from the South African and African perspectives. In 2013–2017 he served as the Chairperson of the Board of the African Network for Internationalisation of Education (ANIE). He currently serves as the chairperson of the Education Deans' Forum of South Africa. He has published a singled authored book titled "Democratising higher education policy, constraints of reform in post-apartheid South Africa" by (Routledge); three edited scholarly books on higher education and more than 40 articles in journal articles, book chapters, and popular media.

Roland Sintos Coloma is a tenured Full Professor of Teacher Education at Wayne State University in Detroit, Michigan. A scholar of history, cultural studies, and education, his research addresses critical questions of race, gender, and sexuality from transnational and intersectional perspectives. His publications include *Asian Canadian Studies Reader* (2017), *Filipinos in Canada: Disturbing Invisibility* (2012), and *Postcolonial Challenges in Education* (2009). His articles have been published in top-ranked peer-reviewed journals, including *Curriculum Inquiry*, *Discourse: Studies in the Cultural Politics of Education*, *Educational Studies*, *Educational Theory*, *History of Education Quarterly*, *International Journal of Qualitative Studies in Education*, *Paedagogica Historica*, and *Race Ethnicity and Education*. He has successfully garnered over \$2 million of external funding from federal, education, and nonprofit agencies, including the US Department of Education, National Education Association, Spencer Foundation, and Schultz Family Foundation as part of the Bill & Melinda Gates Foundation's Grand Economic Challenges. Roland has served in various university leadership roles as an assistant dean, department chair, graduate coordinator, and center codirector. He was president of the American Educational Studies Association (2018–19), editor of the *Educational Studies* journal (2014–17), and program cochair of Division G (Social Context of Education) in the American Educational Research Association (AERA). He received the 2017 Distinguished Scholar Award from the AERA Research on the Education of Asian Pacific Americans SIG and the 2015 Article of the Year Award from the AERA Queer Studies and Education SIG. In 2020, he was appointed to the Governor of Michigan's statewide Asian Pacific American Affairs Commission. Born in the Philippines and raised in California, he completed his PhD in Cultural Studies in Education and Minor in African American and African Studies from The Ohio State University in 2004.

Roger Slee is the Founding Editor of *The International Journal of Inclusive Education* and *The Journal of Disability Studies in Education*. A former Deputy Director-General of Education in Queensland, Australia, he has advised governments on inclusive education policy and practice. His published books include: *The Irregular School*; *Inclusive Education Isn't Dead, It Just Smells Funny*; and *Ethics and Inclusive Education: Disability, Schooling & Justice* (with Gordon Tait). Roger was commissioned by the UNESCO to write the scoping paper for the 2020 Global Education Monitoring Report, *Inclusion and Education*. Roger also held the Chair of Inclusive Education at the Institute of Education, London, and is now the Diamond Jubilee Professor of Disability & Inclusion in the School of Sociology & Social Policy at the University of Leeds.

Ninni Wahlström is a Professor of Education at Linnæus University, Sweden. Her current research focuses on transnational and national policy discourses and their implications for national curriculum and classroom teaching from a perspective of curriculum theory and educational philosophy. Most recent publications are "School and democratic hope: the school as a space for civic literacy" in *European Educational Research Journal* (2022) and Wahlström (Ed.) *Equity, Teaching Practice and the Curriculum*, Routledge (2022).

Lei Wang is Professor and PHD advisor of the Institute of Chemical Education, the College of Chemistry in Beijing Normal University (BNU). She is also the member of Teaching Steering Committee on Basic Education of Ministry of Education of China and the director of its branch Committee on Secondary Chemistry Education, the director assistant of Faculty of Education of BNU, vice director of the Institute of Science Education of BNU, and Chairman of the Chemistry Education Committee of the Chinese Chemical Society. She is one of the chief experts in developing the *Secondary School Chemistry Curriculum Standards* of MOE. She works as the chief editor of high school chemistry textbooks (Shandong Science and Technology Press, 2004 and 2019 editions) and junior high school chemistry project-based learning textbooks (Shanxi Education Press, 2018 edition). She achieved the first prize of the National Basic Education Teaching Achievement Award, the second prize of the National Higher Education Teaching Achievement Award, and the BAOGANG Education Outstanding Teacher Award.

Everard Weber is a retired professor. He has worked in the field of education for more than 40 years. Currently he is a research associate at the University of Johannesburg (UJ) and an academic advisor in the Future Professors Programme (FPP) at UJ. He studied African Languages and History at the University of Cape Town and Comparative and International Education at Harvard University. In South Africa he has worked at Crestway High School in Cape Town, the University of the Witwatersrand, and the University of Pretoria. A recent book is *A home away from home: a community of international and South African university students*. The FPP is a government-sponsored initiative that seeks to develop the next generation of professors and academic leaders in all disciplines, across all universities in South Africa. He is in addition presently conducting fieldwork on curriculum change in South African higher education with Professor Shireen Motala and Dr. Venise Joubert at UJ. This project is grounded in the history of southern Africa and hopes to contribute to the scholarship of postcolonialism.

Ian A.G. Wilkinson is Professor in the Department of Teaching and Learning at The Ohio State University and Honorary Professor in the School of Curriculum and Pedagogy at the University of Auckland, Aotearoa/New Zealand. He has a background in educational psychology with special interests in cognition, instruction, and research methodology as they relate to the study of literacy. He served as coauthor of the influential report, *Becoming a Nation of Readers* (National Academy of Education, 1985). He was Co-Editor of *Reading Research Quarterly* from 2006 to 2012 and was inducted into the Reading Hall of Fame in 2021. His research examines the impact of classroom discussion and dialogue on students' reading comprehension and argument literacy and the implications for professional development of teachers. Recently he coauthored books include *The Most Reasonable Answer: Helping Students Build Better Arguments Together* and *Quality Talk About Text: Discussion Practices for Talking and Thinking About Text*.

David B. Yaden, Jr., PhD, is the *Jewell M. Lewis Endowed Distinguished Professor of Literacy* in the Department of Teaching, Learning and Sociocultural Studies at the University of Arizona. Prior to his present position at the University of Arizona, he held appointments at Emory University, the University of Houston, and the University of Southern California. He served as Co-Editor of the *Journal of Literacy Research*, one of the premier research journals in the field of literacy studies, and was a Principal Investigator in the federally funded Center for the Improvement of Early Reading Achievement (CIERA) where he implemented an early literacy curriculum for linguistically diverse preschoolers in inner-city Los Angeles. He also directed a statewide consortium of researchers from Arizona's major universities in the evaluation of the state's early childhood initiative to evaluate health, developmental, and educational factors contributing to school readiness. His research interests and specializations include developmental issues in early childhood education, the acquisition of literacy and biliteracy in young emergent bilingual children, family literacy, theories of reading disability, microgenetic research design, and the application of complex adaptive systems theory to growth in reading and writing.

Volume 13: Assessment, Evaluation and Accountability

Therese N Hopfenbeck, University of Melbourne, Melbourne, Australia

© 2023 Elsevier Ltd. All rights reserved.

Introduction: An Overview of Educational Assessment, Evaluation, and Accountability

The present section documents recent trends and historic perspectives within educational assessment, evaluation, and accountability studies. The field contains areas on classroom-based assessments, both summative and formative assessment, evaluation studies, alternative assessments, accountability measures, international large-scale studies, and standardized testing. Much of the educational assessment field has historically focused on what teachers do in the classroom, including teachers' instructions and assessment practices, previously referred to as *classroom evaluation* (Natriello, 1987). A related term, *classroom-based assessments*, has also been used, with the main purpose to establish practices which would enhance students' learning and provide feedback on what steps to take in instruction (Black and Wiliam, 1998, 2009). This line of research has also looked at different forms of feedback processes both in classrooms and for students in higher education, with the purpose of documenting what is seen as high-quality feedback within formative assessment processes (Nicol and Macfarlane-Dick, 2006).

The recent decades have witnessed a push for outcome data collected through large-scale studies in order to monitor and evaluate education systems nationally, in school districts and at school level, and to be able to compare outcomes across countries, districts, and schools. The increasing focus upon international comparison and pressure on holding teachers, school leaders, and district leaders accountable for students' performance, has become one of the most researched fields within the educational assessment, as reflected in the many chapters in this section.

Further, there has been a call for increasing teachers' assessment literacy and to better understand and use information from both classroom-based assessments and standardized testing programs, i.e., national and international assessments. Some have even argued that teachers need to play a more active role in high-stakes summative assessment because even the best external tests are bound to be of limited validity (Black, 2013, p. 171). Understanding the field of educational assessment therefore involves knowledge of how classroom-based assessment and standardized testing work together, both in terms of practice and policy. This section on *Educational Assessment, Evaluation and Accountability* provides such knowledge.

The current section contains of eight parts; (1) Assessment and Learning, (2) Educational Assessment—Assessment Activities, (3) Educational Assessment—Policy and Practice, (4) Educational Accountability—Purpose, Models, and Data use, (5) Philosophical and Theoretical Underpinnings of Assessment, Evaluation, and Accountability, (6) Educational Evaluation—Contemporary Themes in Evaluation, (7) Educational Evaluation—Key concepts and practices, and (8) Educational Accountability—Global trends and future directions.

The first four parts (1, 2, 3, and 4) have chapters outlining what historically was seen as one of the most important areas for teachers, *classroom-based assessment*, what every teacher should know and be able to do, to improve students' learning. The first part of this overview therefore provides chapters covering what generally has been viewed as necessary skills for teachers with respect to assessment literacy. It includes chapters outlining the theoretical and conceptual work around formative assessment, also known as "assessment for learning," with examples of how students can enhance their learning through self-assessments, peer-assessments, self-regulation, and other more dialogical practices (Allal, 2023; James, 2023; Topping, 2023). Other chapters also outline theoretically and empirically how different forms of feedback can support students' learning, when used timely and with high quality (Ajjawi et al., 2023; Gamløy and Vattøy, 2023). The section further includes chapters on different forms of assessments, and outlines alternative ways of assessing both student outcomes and teachers' instruction and teaching (McGrane, 2023).

Classroom-based assessment research has focused upon the differences in formative and summative assessment, and how such practices can enhance or prevent students' learning. While formative assessment practices have often been characterized as low-stakes, as these assessment practices usually had no high-stake consequences for students or teachers, summative assessment practices are usually seen as high-stakes. Standardized external test results are intended to determine not only the individual student's future possibilities for university places and future careers but aggregated test results may also be used to rank and compare schools in districts, states, or countries. Several of the chapters in this section discuss the tension between high-stakes and low-stakes assessment and the balance between formative and summative assessment practices.

The current section further includes new empirical studies on the experiences from the Global South, where large-scale implementation of assessment for learning practices have offered new knowledge on the possibilities and limitations of these practices. These chapters challenge the status quo of what has been seen as ideals for assessment practices as they question the notion that western practices can be implemented in the Global South. They even make a call for rethinking what is seen as "best practices" of educational assessment (Halai et al., 2023; Klinger and Nicholas, 2023).

From the teacher's perspective, some of the challenges with classroom-based assessment are linked to national and international assessments. In the final four parts (5, 6, 7, and 8) of this section, we find chapters on evaluation studies and future global trends. Globally, we have seen a trend where international large-scale studies provide data to governments and policy-makers, from country and districts at an aggregated level (OECD, 1999; IEA, 2021). While Sherer and Nilsen (2023) argues that the first international

large-scale studies, conducted by the international organization IEA, had more of a research focus rather than policy impact, the OECD studies, such as PISA, have had more of a policy impact and have also received more media attention (Addey et al., 2017).

The primary intention of these datasets has been to inform policy-makers about trends over time, and monitor systems on how they perform. The second section provides an overview of different perspectives from international large-scale studies, the use of such data, and how different accountability measures are now put in place to ensure students' performance are monitored. Some of the chapters provide a critical perspective on these measures, as they document how large-scale standardized assessment can benefit educational stakeholders with valuable data about students' performance when used well, but simultaneously, data can be misused by policy-makers if set targets are not met (Ozga, 2023). Some chapters further explore and question the validity of such data, and to what extent different stakeholders have the necessary knowledge to interpret, use, and act upon the data provided. The second part of this section therefore also includes chapters on validity and assessment, with important discussions on what is needed for education systems to become fair, valid, and reliable. It includes chapters on what is known as intelligent accountability, with examples on how different stakeholders can use assessment data to improve achievement and learning on all levels within an education system.

While international large-scale assessment studies (ILSAs) have in some of the literature been described as low-stake tests as they compare countries rather than evaluate schools, teachers, or students, the use of these rankings as described in some chapters in this section clearly demonstrate the increasingly high-stakes role of ILSAs as policy-makers have used results from the studies to make calls for policy changes in the education systems.

Some chapters do warn that the field of educational assessment runs the risk of being rather ethnocentric, with groups of scholars working in different countries pursuing isolated agendas. One of the challenges for the field of educational assessment will therefore be to bridge the gap between different research groups, to share knowledge and disseminate results and data in a way which enhances transparency. It will also include working with researchers across the globe and acknowledge the importance of different cultures and contexts to better understand how to develop and interpret different assessments. Indeed, Jude (2023) suggests that the increasing number of immigrant students globally demonstrates that one of the most pressing challenges for the future is to secure equality through education policies. With references to the UN sustainable development goals, which states "equality for all and quality in education" (United Nations, 2015), Jude (2023) outlines the importance of using ILSA studies to monitor the progress across countries in order to create education systems that can support a more heterogeneous population and help students develop intercultural skills.

Educational assessment continues to drive what is taught in classrooms, and hence what students learn. The coming decades will determine the balance between classroom-based assessment and ILSAs, their use and interpretations. Those who are in charge of what counts in educational assessment have the power to influence what students will study and learn. The chapters in this section make a powerful call for more intelligent use of assessment data, broader research collaboration, increased focus upon equality for all students and the further development of assessment practices in the classroom which support students' agency.

Introduction

Formative assessment has become increasingly popular as strategy for improving teaching and learning since the popularization of that concept deriving from the publication of a research review in an academic journal (Black and Wiliam, 1998a), a summary of that work in a magazine for educators and policy makers (Black and Wiliam, 1998b), and an update to that work (Black and Wiliam, 2018). It is likely that no other educational intervention in the last 20 years has spawned greater research interest, commercial development, and practitioner appeal as has formative assessment.

Ironically, however, it is also likely there is no other concept introduced over the last two decades for which there is greater disagreement as to definition, greater disputes about efficacy, or greater deliberation about implementation.

The following sections of this entry provide the framework necessary for understanding and using formative assessment. First, a section called **Foundational concepts** lays the groundwork for the specialized practice of formative assessment by defining concepts from which it derives: inference, testing, and assessment. The next section traces the historical roots of formative assessment. Drawing on these foundations, section **Current concepts, confusions, and controversies** presents a contemporary, consensus definition of the concept, followed by a brief overview of some lingering confusions and controversies surrounding formative assessment. Section **Recent research on formative assessment** summarizes some of the most recent research on the practice of formative assessment, focusing exclusively on findings published since Black and Wiliam's (1998a) seminal review. A final section suggests conclusions and next steps for formative assessment research and practice.

Foundational concepts

As used in the field of education, formative assessment comprises a set of specialized procedures for gathering information about learning. To be sure, the preceding is not an adequate definition of formative assessment and a more complete definition will be provided in a subsequent section. In order to fully introduce a definition of formative assessment, however, it is important to locate that concept among a constellation of relevant, superordinate concepts within the broader field of educational measurement. In the following paragraphs, three related concepts are defined: inference, testing, and assessment.

Inference

A first essential concept that underlies all educational measurement is inference. The term *inference* can be defined as the process by which a tentative conclusion is reached based on incomplete, but pertinent information. Whenever any information is collected and conclusions drawn about student learning, inference takes place. This is the case because, typically, it is only practical to gather

a small sample of what might be observed regarding some characteristic relevant to learning in schools (e.g., mathematics problem solving, laboratory skills, essay writing ability, and so on). A teacher may seek to understand a student's proficiency at solving math problems, may want to evaluate a student's safety in the lab, or may need to assign grades in English composition. However, although it might be desirable for the teacher to observe the student solving dozens of math problems, conducting numerous lab experiments, or writing many essays, there is limited time for either the student to generate that information or the teacher to review it. Nonetheless, decisions about math homework, lab safety, and English Comp placements must still be made. Thus, it is nearly always the case that educators must come to those conclusions or make those decisions based on limited samples of information. The act of going from that smaller set of observations to a conclusion about a student's standing on some characteristic is called inference. The measurement specialist Benjamin Wright (1998) described inference this way:

I don't want to know which questions you answered correctly. I want to know how much ... you know. I need to leap from what I know and don't want to what I want but can't know. That's called inference.

In education, because complete information about student learning is never available, inference is a ubiquitous activity. From at least one perspective, it is also a desirable one; that is, gathering and correctly interpreting all possible information about a student would be prohibitive in terms of cost, time, and burden for all involved, so the practice of inference-making is an efficient process. Nonetheless, because they are based on limited samples of information, inferences should always be considered tentative and subject to reconsideration when additional information relevant to the conclusion becomes available.

Test

The second concept relevant to consideration of formative assessment is testing. Testing is a process often used by educators for gathering information—and making inferences—about student learning. A *test* is the tool used in that process for collecting a systematic sample of information about the characteristic of interest, such as a students' knowledge, skill, ability, interest, or other attribute which cannot be directly measured.

There are nearly an infinite number of configurations that would qualify as a test. A slate of multiple-choice questions administered under strict time and location requirements is only one test format—and certainly not the most informative for every information need. Surveys, performance tasks, essays, interviews, class discussions, direct observations—all of these and more qualify as tests to the extent that they are conducted and scored in systematic ways that foster accuracy and dependability of the conclusions based on their results.

Finally, because tests typically capture only a small portion of what could be gathered, and because the inferences based on test results can lead to consequential decisions about students, it is essential that the sample of information elicited by a test is carefully structured—whether the test is informal (e.g., the observation of clinical technique) or formal (e.g., a standardized college admissions test). Although beyond the scope of this entry, comprehensive information on the procedures and guidelines that characterize careful assessment development are treated extensively elsewhere (see, e.g., Lane et al., 2015).

Assessment

The final foundational concept presented here is that of assessment. Although often used synonymously with “test”, assessment is far broader in meaning. Prior to its use in education contexts, the term assessment was correctly applied in many other fields, including finance, medicine, and elsewhere. For example, when a retirement advisor conducts a financial assessment for a client, he or she examines a diverse set of variables (e.g., personal savings, stock holdings, IRAs and other investments, along with liabilities, retirement goals and timeline) to provide an overall summary and plan for the client. In the field of medicine, health care workers in an emergency department must rapidly perform an assessment of incoming patients. The assessments may take the form of measurements of blood pressure, temperature, respirations, reflexes, blood tests, x-rays, and other diagnostic procedures. The aim of gathering these disparate pieces of information (i.e., the results of various tests), is to produce a synthesis of the information in support of a conclusion about the present (i.e., financial position, diagnosis) and path for the future (i.e., retirement plan, treatment).

In short, *assessment* is the process of collecting and synthesizing many samples of information—that is, many tests—toward a specific purpose. In the context of education, Cizek (1997, p. 10) has defined assessment as “the planned process of gathering and synthesizing information relevant to the purposes of: discovering and documenting students' strengths and weaknesses; planning and enhancing instruction; or evaluating and making decisions about students” (Cizek, 1997, p. 10).

The term “assessment” is used accurately in education to describe the work of Individualized Educational Planning (IEP) team meetings. Such meetings might involve the teacher of a student relating observations of the student's in-class achievement and behavior, the parents of the student providing insights on the student's at home experiences, the school psychologist explaining the results of cognitive testing that was performed, and so on. Each of these contributions can be thought of as providing “test” information, because each is a sample of information about a student. The assessment involves aggregating all of the diverse sources of information, arriving at some tentative conclusions about what is happening for the student and developing tentative plans regarding appropriate placements, interventions, and supports.

Although each term has a specific, technical meaning that warranted consideration as conceptual background, it is likely that the terms “test” and “assessment” have become so pervasively used as synonyms that insistence technical accuracy would serve no

purpose. Indeed, even as regards the topic of this entry, although it would often be more conceptually accurate to refer to a “formative test”, the more familiar “formative assessment” label will be adopted.

Origins of formative assessment

The origin of the term formative assessment in education contexts has been traced by Cizek (2010), who observed that the roots of formative assessment can be traced to a chapter by Michael Scriven that appeared in a monograph series produced by the American Educational Research Association (AERA). In that source, Scriven (1967) coined the term, *formative evaluation*. Given the volume’s focus on curriculum evaluation, it is unsurprising that Scriven’s use of the term was in the context of program evaluation—in particular, evaluation of the effectiveness of school-based curricula and other educational program features and their effects on student achievement.

The concept of formative evaluation gained greater attention when it was popularized via the influential volume by Benjamin Bloom and his associates entitled the *Handbook of Formative and Summative Evaluation of Student Learning* (Bloom et al., 1971). Although that volume is perhaps most widely-known for its treatment of taxonomies of educational objectives introduced previously by Bloom (1956), it can also be recognized as providing one of the first explications of two concepts—formative and summative evaluation. Bloom et al. (1971) defined the term “summative” in way that subsumed, but went beyond Scriven’s comparatively narrower focus on evaluation of programs, extending the use of the term to the assessment of learning and to individual students:

We have chosen the term “summative evaluation” to indicate the type of evaluation used *at the end* of a term, course, or program for purposes of grading, certification, evaluation of progress, or research on the effectiveness of a curriculum, course of study, or educational plan [T]he essential characteristic of summative evaluation is that a judgment is made about the student, teacher, or curriculum with regard to the effectiveness of learning or instruction *after* the learning or instruction has taken place (p. 117, emphasis added).

Bloom et al. (1971) then distinguished summative evaluations—arguably the most prominent assessments at that time—from evaluations intended to serve a different purpose. According to Bloom et al. “formative evaluation is for us the use of systematic evaluation *in the process* of curriculum construction, teaching and learning *for the purpose of improving* any of these three processes” (1971, p. 118, emphasis added). This essential difference in the nature of summative and formative activities has been expressed pithily by Stake who noted that: “When the cook tastes the soup, that’s formative: When the guests taste the soup, that’s summative” (quoted in Scriven, 1991, p. 169).

Although some residual connection between the concept of “formative” and the field of program evaluation is still apparent in Bloom’s work, it is equally clear that Bloom’s expanded definition foreshadowed the linkages and uses of a formative approach for the assessment of individual students and for improving teaching and learning. According to Grant and Gareis (2014), an evolution in usage from *formative evaluation* to *formative assessment* began in the 1980s as educational researchers shifted focus from program evaluation to student learning and achievement. Importantly, the early distinction made by Bloom between summative (connoting an activity occurring “at the end” for purposes of assigning final grades and so on) and formative (connoting activity “in the process” for purposes of changing or improving the process) is now well-established. And, since the 1980s, formative assessment in educational settings has flourished and become a specialized field of academic study and school-based practice.

Current concepts, confusions, and controversies

Clear, consensus conceptualizations of formative assessment have been somewhat elusive. A recent feature on formative assessment in *Education Week* began by noting that “If you ask five teachers what formative assessment is, you’re likely to get five different answers” (Gerwertz, 2015, p. S2). Differences in definition are not only held by educators, but also evident in scholarly and professional writing on the topic. For example, in their book on formative assessment, Cizek et al. (2019) provide a table listing 10 varying definitions of formative assessment published in the professional literature since 2006. In a similar vein, a recent commentary on formative assessment theory and practice noted that:

The literature base on using formative assessment for instructional and intervention decisions is formidable, but the history of the practice of formative assessment is spotty. Even with the pressures of high-stakes accountability, its definition is fuzzy, its adoption is inconsistent, and the prognosis for future use is questionable.

Dorn (2010, p. 325).

One particularly troubling aspect of popular notions of student formative assessment is that the term has been used to describe a diverse array of products and practices ranging from commercially-produced, multiple-choice item banks from which teacher can create customized quizzes, benchmark tests, and drill materials, to guidelines for student creation of rubrics to evaluate drafts of their writing (and for assessing and providing feedback on the writing of their peers).

Accordingly, one difficulty in defining formative assessment is that whereas the preceding activities *might* have a formative aspect, they might also be conducted in such a way as to provide little, if any, “in process” information for adjusting or improving learning or instruction by teachers, and typically scant information that is truly formative for students. Although several assessment specialists have warned against accepting anything *labeled* “formative” as actually fulfilling a formative purpose (see, e.g., [Popham, 2006](#); [Shepard, 2005](#)), the concern persists. Thus, clarity about what formative assessment is—as well as what it is not—is essential. The following sections focus on formative assessment for students. Three distinguishing features of formative assessment are described and a consensus definition of the term is provided.

Distinguishing characteristic 1—primary purpose

A first distinguishing feature of contemporary definitions of formative assessment is the centrality of purpose. Whereas both summative and formative assessments share the aim of gathering information about student learning, the *reason* for gathering the information and how it will be used are key considerations in distinguishing between summative and formative activities. A summative assessment is any system of information gathering that is administered at the end of some unit of instruction (e.g., unit, semester, school year) and has as its primary purpose to categorize, label, or otherwise produce an evaluative conclusion about the merit, value, achievement or performance of a student or system. That is, the primary purpose of summative assessment is obtain a measurement of achievement to be used in decision making, assigning grades, awarding or denying a diploma, allocating compensation, or similar actions. In contrast, formative assessment describes information gathering that occurs “midstream” or in the course of some unit of instruction and has as its primary at least one of the following: to identify the test taker’s strengths and weaknesses, to assist educators in the planning of subsequent instruction, to aid students in guiding their own learning, revising their work, gaining self-evaluation skills, or fostering increased autonomy and responsibility for their learning. This distinction in primary purpose has, in other works, been described as a difference of assessment *of* learning versus assessment *for* learning ([Assessment Reform Group, 1999](#); [Stiggins, 2005](#)).

Although this distinction between summative and formative assessment regarding primary purpose is essential, it is not exclusive. That is, it is possible for assessments with primarily a summative purpose to serve a secondary, formative purpose; likewise, it is possible for assessments intended primarily to provide formative information to serve a secondary, summative purpose.¹

Distinguishing characteristic 2—timing and feedback

As is perhaps apparent from the distinction made previously between assessment *for* learning and assessment *of* learning, the second distinguishing difference between formative and summative assessment involves the timing of the activity. Formative assessment occurs during instructional activities. Feedback from formative assessment activities occurs during learning and points to areas of success, progress toward goals, and areas for improvement. Summative assessment occurs at the end of an instructional period (e.g., class, unit, semester), after instruction has taken place. Whereas corrective feedback is a hallmark of formative assessment, summative assessment may not be accompanied by any corrective feedback on performance other than an evaluative indicator such as a grade, award, or placement.

Distinguishing characteristic 3—student involvement

The final distinguishing characteristic of note regarding formative assessment is that of student involvement. This characteristic is perhaps the least well understood, accepted, or enacted, or all the features of formative assessment—and yet it is the characteristic that may be primarily responsible for the efficacy of the practice.

By “student involvement” we refer to several related aspects. First, effective formative assessment entails empowering students to articulate their own learning goals or, at minimum, aiding them in understanding the goals set for them, where they stand currently in relation to those goals, and what next steps will enable them to make progress toward the goals. Effective formative assessment provides explicit assistance to students in developing meta-cognitive skills and self-regulation of their own learning (see e.g., [Zimmerman, 1986](#)).

Second, effective formative assessment engages students via self-assessment. At minimum, formative assessment affords students opportunities to understand the evaluative norms applied to work in a discipline, to internalize those norms, and to apply them accurately to the work they produce ([Andrade, 2010, 2019](#)). At times, this kind of evaluation may be broadened to include peer evaluation, where trusted, critical colleagues who also have a good grasp of the evaluative norms can provide feedback on each other’s work. And, self-assessment may be a particularly powerful formative assessment strategy when students actively take part in the development of the specific evaluation guidelines (e.g., grading frameworks, scoring rubrics, etc.) that will be applied to their work. A good deal of research has taken place on this topic across diverse areas such as writing and the performing and creative arts (see, e.g., [Andrade, 2019](#); [Andrade et al., 2008](#)).

¹Although, see [Cizek et al. \(2019\)](#) for cautions on using formative assessments for summative purposes.

Formative assessment: a definition

Given these distinguishing characteristics, it is possible to derive a definition of formative assessment that is broad enough to cover assessment information for use by teachers and by students, and to incorporate the elements most likely to produce the hoped-for efficacy of formative assessment practice. The following definition is modified only slightly from that provided in [Cizek et al. \(2019\)](#):

Formative assessment comprises a diverse array of generic and discipline-specific information gathering practices, ideally nested within a planned assessment system, the primary aim of which is to support teachers' and students' inferences about learning and conceptual organization, strengths, and diagnosis of weaknesses and areas for improvement. Formative assessment yields information that educators can use in instructional planning and students can use in deepening their understandings, improving their achievement, taking responsibility for, and self-regulating their learning.

The preceding definition not only addresses the three distinguishing characteristics noted earlier, but foreshadows an emerging characteristic of formative assessment: the notion that formative assessment is not comprised exclusively of generic practices, but also may take different forms depending on the specific disciplinary area in which the information gathering takes place. A number of scholars have begun to explore this topic (see e.g., [Andrade et al., 2019a,b](#); [Heritage and Wiley, 2020](#)). The specific aspects of formative assessment that may differ across disciplines is clearly an area of current and likely future research.

Recent research on formative assessment

In general, studies have found fairly consistent positive effects of formative assessment on student achievement ([Graham et al., 2015](#); [Kingston and Nash, 2011](#); [Klute et al., 2017](#); [Weurlander et al., 2012](#); [Wiliam, 2011](#)). But what accounts for the positive effects? Over the past decade, the three distinguishing characteristics of formative assessment have received increasing attention, as researchers have sought and gained refined notions of the mechanism of action for formative assessment. This section provides a review across the most recent 10 years of empirical studies that have explored the efficacy of formative assessment on student learning with special attention to the distinguishing characteristics identified in the previous section. In the following sections, four areas of contemporary research on formative assessment are reviewed: (1) critical features of effective formative assessment; (2) the relationship between formative assessment and self-regulated learning, (3) discipline-specific aspects of formative assessment; and (4) technology-enhanced formative assessment.

Critical features of effective formative assessment

A number of research reviews and opinion papers have discussed the efficacy of formative assessment. Although a wealth of information already exists regarding the features of effective formative assessment generally, knowledge about what constitutes effective formative assessment continues to expand. Over the past decade, new research evidence has been emerging about several features that have gained empirical support for the design and implementation of effective formative assessment. These include: clearly defined purpose, design, and format of formative assessment in different classroom contexts ([Lane et al., 2019](#)); the use of explicit criteria for students to use in planning, monitoring, and evaluating own learning ([Panadero and Romero, 2014](#); [Jonsson, 2014](#)); the instructor's role in modeling self-assessment and the use of rubrics and descriptive feedback ([Panadero and Jonsson, 2013](#); [Panadero et al., 2016](#)); and the use of positive feedback under learner-centered assessment methods ([Pereira et al., 2016](#)). Finally, [Black and Wiliam \(2018\)](#) substantially extended their earlier work on formative assessment by locating it within a broader theoretical perspective. (See also a history and introduction to their work by [Hopfenbeck, 2018](#)). Black and Wiliam propose a model in which the design of learning activities and assessments is influenced by three factors: (1) relevant educational theories (e.g., learning theory, pedagogical theory); (2) the specific academic discipline under consideration; and (3) broader educational, political, cultural, and social contexts. They conclude by identifying and discussing issues of policy, practice, and implementation related to formative assessment.

The relationship between formative assessment and self-regulated learning

A recent development has been the exploration of linkages between formative assessment and self-regulated learning (SRL). The theoretical association between these concepts has been addressed by a number of researchers ([Andrade and Brookhart, 2020](#); [Clark, 2012](#); [Panadero et al., 2018](#)). Most recently, a special issue *Assessment in Education: Principles, Policy & Practice* brought together not only the emerging theoretical work, but also included some contemporary empirical studies (see [Brandmo et al., 2020](#)).

There is an abundance of literature exploring the theoretical relationship between formative assessment and SRL compared to the quantity of empirical studies of that relationship (see, e.g., [Panadero et al., 2016, 2017](#)). As formative assessment has also sometimes been called *assessment for learning*, studies using that concept were also included and analyzed.

An overall relationship between formative assessment and SRL was detected: Formative assessment and SRL are closely related, as both formative assessment and SRL "are oriented toward assessing own performance" ([Panadero et al., 2017](#), p. 77). The picture

is somewhat blurry, however, as studies have incorporated different types/tools/components of formative assessment (e.g., feedback, self-assessment, peer-assessment, the use of rubrics, scripts, etc.) to study their associations with the primary features of SRL (e.g., self-evaluation, self-monitoring, cyclical process). Although the research base is only beginning to form, there would seem to be reason for optimism about the relationship between formative assessment that includes an SRL emphasis. For example, a study by [Perry et al. \(2020\)](#) investigating writing performance of third graders found that students in classrooms with higher emphases on SRL and formative assessment demonstrated more sophisticated self-assessment, greater interest, higher levels of self-regulation, and higher quality writing than students in classrooms with lower emphasis on SRL and formative assessment.

A number of researchers have investigated the effectiveness of feedback as an instructional process through literature and meta-analytic work over a period of time ([Black and Wiliam, 1998a](#); [Hattie and Timperley, 2007](#); [Lipnevich et al., 2014](#); [Wiliam, 2011](#)). Overall, feedback—one of the distinguishing characteristics of formative assessment—has often been connected to SRL for measuring student achievement and improvement in learning, and numerous recent studies have provided empirical evidence of the effective use of feedback on student learning (see, e.g., [Evans, 2013](#); [Hudesman et al., 2013](#); [Lipnevich et al., 2014](#); [Pereira et al., 2016](#)). The mechanism of action for this effect was explored by [Orsmond et al. \(2013\)](#) who provided evidence that self-regulation of learning fosters effective learning by engaging students in their own learning processes. They also found that feedback, as an interactive process between learners and teachers, encourages students to make use of feedback for their self-regulation and improvement of learning.

Another distinguishing characteristic of formative assessment, *self-assessment*, has been studied by several researchers. Self-assessment facilitated by rubrics ([Panadero and Jonsson, 2013](#)) and scripts ([Panadero et al., 2012](#)) has been found to be effective for learning SRL skills (e.g., self-reflection, forethought), which subsequently leads to improvement in students' learning ([Panadero et al., 2016](#)). Another study conducted by [Panadero and Romero \(2014\)](#) concluded that self-assessment had statistically significant effects on all three phases of SRL—*forethought*, *performance*, and *self-reflection*. Therefore, it has been argued that promoting students' self-assessment should yield positive effects on student learning, as the process of self-assessment encourages students to plan, monitor, and evaluate their own learning ([Brown and Harris, 2013](#); [Jonsson, 2014](#)).

Discipline-specific formative assessment

The importance of accurately measuring the effect of formative assessment on student learning improvement has been raised by several researchers. For example, the meta-analysis of formative assessment conducted by [Kingston and Nash \(2011\)](#) was critiqued on methodological grounds (see [McMillan et al., 2013](#)), including the fact that the features of formative assessment are often non-transferable from one discipline to another. Increasingly over the last decade, researchers have delved into the differential approaches to formative assessment that account for its effects in specific disciplines (see [Andrade et al., 2019a,b](#); [Bennett, 2011](#); [Coffey et al., 2011](#); [Heritage and Wylie, 2020](#); [Hudesman et al., 2013](#); [Lane et al., 2019](#); [McMillan et al., 2013](#)).

Research on discipline-specific approaches to formative assessment is still developing, so it is too early to identify major trends. Further, most discipline-specific formative assessment research has taken place primarily in the K-12 contexts of science, mathematics, and writing. Studies from two representative disciplines are presented in the following paragraphs.

Science, as a discipline, has been considered to be difficult for both students and teachers as it requires complex and abstract concepts, problem-solving skills, and reconstruction of diverse concepts and links ([Miller, 1991](#)). In science education, helping students to clarify their current knowledge, develop conceptual change, and construct scientifically-accurate ideas are seen as essential components of science learning. Hence, formative assessment that incorporates focused feedback has been considered as one of the crucial elements of teaching and learning in science education ([Bell and Cowie, 2001](#)). However, science teachers have often encountered obstacles such as lack of understanding about formative assessment processes that can be effectively used as instructional practices and lack of science content knowledge that hinders teachers in helping students minimize the gap between new concepts and their prior knowledge ([Coffey et al., 2011](#); [Sabel et al., 2015](#)). As a result, when using formative assessment, science teachers often struggled with providing appropriate guidance and scaffolding to students because they often failed to communicate with students about students' reasoning and misconceptions. To resolve these issues, science education researchers have focused on designing formative assessment activities that can be embedded in the curriculum, and helping teachers improve communication with students ([Sabel et al., 2015](#)). They concluded that embedding formative assessment practices in curriculum with focused feedback can improve the quality of communication between teachers and students in terms of detecting and revising misconceptions, understanding and bridging new concepts and prior knowledge, and demonstrating problem-solving skills around abstract ideas ([Anderson et al., 2014](#); [Sabel et al., 2015](#)). Other researchers have found similar results: If embedded properly in the curriculum and if provided adequate support to students, formative assessment can enhance students' acquisition of science content knowledge and improve learning progressions ([Decristan et al., 2015](#); [Yin et al., 2013](#)).

A similar trend to that observed in science has been found in the domain of mathematics. Lucariello and colleagues conducted a study that administered formative assessment to middle school students to diagnose their misconceptions when learning algebra ([Lucariello et al., 2014](#)). Their formative assessment successfully identified students' misconceptions and how those misconceptions and reasoning errors arose. Their findings enabled teachers to gain insightful understandings about students' misunderstandings which can be later led to developing differentiated instruction for their students. Furthermore, several other studies in mathematics have revealed that diagnosing misconceptions alone is likely insufficient for facilitating the greatest learning gains from formative assessment; specific teacher behaviors that build students' skills in self-regulating their own learning are critical ([Hudesman et al., 2013](#)).

Finally, recent research on formative assessment in the disciplines of science and mathematics has revealed another key element of effective formative assessment: teachers' content knowledge. This element comes into play as educators strive to comprehend students' conceptual understandings, abstract thinking processes, and problem-solving skills, and as teachers are required to craft specific, supportive, constructive, and content-grounded feedback to students.

As a result, across disciplines, recent work in the area of formative assessment has highlighted an increasing need for professional development training for teachers to enhance their understandings about student cognition, learning progressions, and self-regulation, and to enhance their skill in designing and conducting appropriate formative assessments (Hondrich et al., 2016; Lane et al., 2019; Sabel et al., 2015).

Technology-enhanced formative assessment

As technology has enabled shifts in pedagogy from face-to-face settings to online and blended learning, increasing attention is being paid to online and remote assessment. Consequently, in conjunction with increased emphasis on well-designed technology-supported learning environments, some research has begun to focus on the design and effects of technology-enhanced formative assessment (Hwang and Chang, 2011).

The conclusion that formative assessment provides rich information about student learning, progress, and achievement, and the importance of instructional feedback on students' problem-based learning in diverse learning settings (e.g., blended settings, online learning, virtual learning environments) is a key finding in research reviews provided by Spector et al. (2016) and Russell (2010). For example, Russell identified ways in which technology-enhanced formative assessment can be supportive and effective toward students' achievement of their learning goals by: monitoring and reviewing student learning progress; identifying weaknesses, strengths, and misconceptions; providing rapid and timely feedback; and tracing learning progress and collecting information for guiding future learning.

In addition, individual empirical studies have investigated the use of technology-enhanced formative assessment and found that these four functions independently and collectively impacted student achievements under various contexts. For example, Dalby and Swan (2019) applied iPad-based formative assessment to year 10 students in mathematics classes. Results indicated that the use of iPad actually benefitted both teachers and students by providing timely feedback, by facilitating tracking of student learning, and by quickly identifying common misconceptions.

Beyond the direct impact of technology-enhanced formative assessment on academic achievement, studies have shown the indirect effects of technology-enhanced formative assessment on factors associated with academic improvement such as student attitude toward learning goals, classroom behavior, and other variables. One example can be found from the study conducted by Tempelaar et al. (2018). These authors investigated relationships between trace data generated by formative assessment using e-tutorials and learning dispositions (a term that refers to individual learner characteristics including affective, behavioral, and cognitive that influence every learning process). The authors reported that the formative assessments contributed to better academic performance of undergraduate students in mathematics and statistics classes. The e-tutorials constituted rapid and important feedback to individual student, provided procedural records of student learning, and anticipated learning for further improvement. In a similar vein, Chen et al. (2019) conducted a study that implemented tablet-based formative assessment system to improve student academic performance by enhancing positive classroom behaviors. The authors concluded that the tablet-based classroom behavior management system (CBMS) positively influenced student's positive classroom behaviors across both short- and long-term periods. The use of tablet-based CBMS also resulted in improved learning outcomes by providing frequent and real-time feedback along with the recorded behavior ratings on a daily basis. The authors suggest that this was made possible because the technology significantly reduced the administrative load of the teachers and enhanced student engagement in the classroom activities.

Conclusions and future of formative assessment

This history of formative assessment can be traced to the introduction by Scriven (1967) of the concept of formative evaluation. In the late 1990s, and after decades of implementation of summative assessment to leverage achievement gains, formative assessment began to receive increased attention because of its potential power to improve teaching and learning.

At present, however, formative assessment is a concept that does not have a universally agreed-upon meaning. In this chapter, we reviewed some key elements of effective formative assessment, including:

- * encouraging student responsibility for their learning;
- * communicating clear, specific learning goals;
- * providing timely, detailed, and constructive feedback to students;
- * instructing students in how to conduct accurate self-assessment of progress toward learning goals; and
- * teacher use of assessment information to enhance instructional planning and practices.

As is evident from this list, authentic formative assessment comprises more than merely more frequent, shorter, or lower-stakes summative assessments such as quizzes, classroom tests, or homework assignments. Rather, formative assessment that has the greatest potential to increase learning is one part of, and implemented within, an educational curriculum, instruction, and assessment ecosystem in which all aspects have distinct purposes and are thoroughly integrated. Although the earliest estimates of the efficacy of

formative assessment may have been overstated, research on formative assessment—if implemented with fidelity with respect to its key elements—has demonstrated that it can be a powerful classroom-based intervention.

Current research on formative assessment has largely focused on four topics including: its relationship to self-regulated learning, formative assessment practices specific to individual disciplines, crucial features that account for the efficacy of formative assessment, and the role of evolving technologies. Overall, the themes evident in current research suggest that formative assessment should be designed to encourage teachers and students to actively communicate about the processes of teaching and learning. For teachers, recognizing whether they are accurately diagnosing students' understanding and misconceptions, and whether they are providing appropriate feedback and instructional guidance to students should be prioritized. For students, taking the lead of their learning and initiating improvement of their learning should be prioritized. By doing so, formative assessment can be most useful and beneficial to both teachers and students.

For the future, it is likely that there will be continuing research emphasis on these four topics. However, in addition, it seems appropriate to recommend that not only additional academic study of formative assessment should continue, but that a new effort must be undertaken. Toward the goals of addressing lingering confusion about the nature of formative assessment, providing educators with effective tools for enhancing learning and instruction, and enhancing the utility of assessment information for guiding educational policy and practice, it is recommended that:

- (1) coursework in assessment be required as part of educator preparation programs;
- (2) pre-service preparation experiences for educators (in particular, teachers and principals) with substantial emphasis on effective formative assessment practices should be developed, tested, and included within assessment-focused coursework or in discipline-specific pedagogical training;
- (3) professional development materials covering contemporary best practices in formative assessment should be developed, tested, and provided for in-service educators; and
- (4) educational leaders at state and local levels should review and redesign, as needed, coherent curriculum/assessment/instruction ecosystems where all components (especially diagnostic, formative, and summative components) provide non-redundant, relevant, and actionable information in the service of classroom decision making and educational policy making.

Formative assessment was initially introduced as a strategy for teachers to gain information about student learning and to use that information to refine instruction. Surely that is still a valuable goal to be pursued. However, ultimately, it is likely the greatest potential of formative assessment lies in its power to change students' own abilities to establish, monitor, and accurately evaluate their learning. To the extent that they are provided with the metacognitive and self-regulation skills that are a key part of formative assessment practice, they will not only be well positioned for greater achievement in their elementary and secondary school years, but well prepared with the self-guided, lifelong-learning orientation that will serve them in future educational and career contexts.

Introduction

This contribution is particularly concerned with the verbs “to assess” and “to learn” and the relationships between the processes they entail in theory and practice. The focus is first on learning and then on the implications for assessment practice. The rationale for this is that education, at whatever level, from early years to adult learning, needs to start from a clear conception of aims and purposes, and then proceed to create curricula and learning opportunities coherent with those goals. Ways of assessing the achievement of those goals (assessment of learning) or ways of assessing that contribute to learning (assessment for learning) also need to serve these educational purposes. Therefore, educational aims, curricula, pedagogical practices, conceptions of learning, and assessment all need to be aligned. Consideration of what learning is, in different contexts, is important for making good choices about assessment tools and practices.

The following sections identify a number of different views of learning and then explore their implications for assessment, taking account of the importance of the variety of aims and learning objectives in different sectors, domains and subject areas. The concept of “learning how to learn” is then explored, together with recent expressions in assessment practice.

The main sources for these inquiries are a series of publications on these themes by the author [James \(2006, 2008, 2012a\)](#) including an entry in the third edition of this encyclopedia ([James, 2010](#)).

Theories of learning and implications for assessment

The first point to make is that many assessments, such as ability and aptitude tests, are not underpinned by explicit theories of learning at all. They were developed to measure mental qualities, such as intelligence, which were believed to be innate traits. They were designed to predict capacity to learn and future success but were not thought to be the products of learning themselves. Indeed they were often designed to screen out the effects of learning, in order to identify candidates with potential rather than privileged access to resources, although it is debatable whether this can ever be wholly achieved. The uses of such assessments, now as in the past, are largely concerned with selection e.g., choosing among candidates those most likely to fulfill the requirements for courses, jobs or promotions, or those who would benefit from special needs support. This approach to assessment is sometimes referred to as “differential”. The technology associated with it is “psychometrics”—literally the “measurement of mind”. As the term suggests it draws heavily on psychology as the foundation discipline.

Psychometrics and cognitive sciences play important parts in the development of assessment and measurement, but other disciplinary perspectives have a role too. Approaches derived from social theory, anthropology, philosophy, and sociology also make a contribution, especially in cultures that value community, as in the East, over individualism, as in the West. For instance, in Russia there has long been debate about the relative importance of “upbringing”, a social good, and “education”, as an individual good. [Anna Sfard’s \(1998\)](#) seminal paper on metaphors of education also makes a key distinction between learning as (individual) acquisition and learning as (social) participation. But, crucially, she points to the dangers of choosing to adhere to just one of these positions.

These themes play out in the following discussions of learning and assessment, and learning to learn.

Chris Watkins (2003) differentiates three views of learning: learning as being taught (equivalent to Sfard's acquisition metaphor); learning as individual sense-making; and learning as building knowledge as part of doing things with others (equivalent to Sfard's participation metaphor). These three views can also be categorized according to their theoretical underpinnings, most usually as behaviorist, cognitive constructivist, and sociocultural or situated. Each of these three views of learning has different implications for assessment practice.

Learning as acquiring what is taught, and implications for assessment

Two different sets of assumptions underpin this view of learning but both share a preoccupation with what is taught, and how well knowledge, both declarative/propositional (knowing that) and procedural (knowing how), is absorbed by learners. Learning is regarded largely as the acquisition of what the teacher or trainer wants to teach and little attention is paid to whether, or how, this knowledge might be modified in the process. Thus learners are regarded as rather passive and success is judged by the extent to which they acquire the knowledge and reproduce the behaviors that the teacher intended.

Folk views of learning

The first set of assumptions is not based on any evidence-informed theory of learning, but rather a folk psychology that regards the brain or mind (the two are not always clearly distinguished) as a kind of vessel into which information is poured. Learning is assumed to have occurred when this knowledge is retained. Perhaps the most explicit expression of this view is found in Charles Dickens' novel, *Hard Times*, in which Gradgrind describes children's minds as like little pitchers to be filled full of facts. Although this is a caricature, there are still a lot of people who hold something like this view.

Of course, learning does involve memory. Eric Kandel (2006), who won a Nobel Prize for his research on memory, emphasizes how much memory matters to our sense of being human. Remembering things is fundamental. What is more questionable is that learners can, or should, always remember things in exactly the same way as taught by their teachers, and be assessed on this. We need not be against the memorization of facts and information, and the development of routines, if we nevertheless want to argue for more complex and nuanced views of learning and assessment.

Behaviorist views of learning

A second set of assumptions that underpin a view of learning as acquisition of what is taught is derived from research evidence within a tradition known as behaviorism. This perspective was derived from a concern to develop a proper science of human behavior based on observation and experiment. Mental processes are not directly observable so they were excluded from investigation.

The basic tenet of behaviorism is that learning can be viewed as conditioned response to external stimuli. In other words, if a particular stimulus produces a response, the recurrence of the stimulus, or something closely associated with it, will cause the response to be repeated. In Pavlov's dogs, the presentation of food caused them to salivate but, over time, after repeated occasions when the food was presented while a bell was rung, the ringing of a bell alone caused them to salivate. Applied to human learning, this theory has been used successfully in situations where a particular behavioral response is sought. Rewards "condition" desired responses, and punishments, or more commonly the withholding of rewards, extinguish undesired responses. Repetition of the stimulus makes the response habitual; hence the value of repeated practice. Eventually the response is so automatic that it can be produced at speed.

These ideas, applied to human learning, sound somewhat old fashioned today (although they are still the basis of successful training of dogs). However, while theory has moved on, practice stemming from it has persisted, and sometimes for good reason. There are times when it is legitimate to expect people to learn to behave in particular ways, instantly, and without worrying too much about the whys and wherefores. As every parent knows, there are times when a repeated instruction, the sharp rebuke, or non-specific praise elicits a behavior that keeps a child safe—from falling under a car, for instance. Furthermore, in a world where there is so much to know and understand, individuals have to make strategic judgments about what they want to understand in depth and what they will be content to know only "on the surface" or as a conditioned response. And this may vary from person to person and context to context.

As with folk psychology, rote learning is associated with the behaviorist approach but there are other features as well. For example, behaviorism assumes that a complex skill can be taught by being broken down into components, each of which can be taught separately then re-assembled. Another assumption is that if an idea or practice is common to many contexts, it is most economical to teach it separately so that it can then be applied in many situations. Moreover, it is considered best to learn basic facts and skills first, then build more sophisticated knowledge and practice on this foundation.

Implications for assessment

The assumptions and beliefs about learning, outlined above, lead to equivalent assumptions about the kinds of assessment practice that are most appropriate. James (2008), labeled this "first generation assessment":

- The learning of the individual is assessed; performance that is influenced by others is regarded as cheating.
- The focus is on performance under test conditions.

- Performance tends to be defined as demonstration of ability to recall facts and information, or to demonstrate skills.
- Tests or tasks are specially constructed for the purpose of assessment and are scheduled at the end of a course or sequence of learning; they are regarded as separate from learning.
- Preparation for tests may involve practice, for example by using past papers, but results on these will not count toward a score or grade.
- Tests are time-limited, on the assumption that speed of completion of the tasks indicates that the learning is well established.
- No access to materials is allowed other than those needed to do the immediate task because it is expected that knowledge can be recalled from memory, or skills performed.
- Questions or tasks for completion are organized in a hierarchy of difficulty, starting with the least difficult, often in the form of short response or multiple-choice items.
- Responses or performances are assessed as correct or incorrect and results from a test are aggregated to give a score enabling comparison with other learners (norm-referenced), against a standard (criterion-referenced) or against the learner's own previous performance (ipsative referenced). Sometimes these referencing systems are combined e.g., norm with criterion referencing, as in most summative assessments for the award of leaving certificates or credentials.
- It may be possible to infer areas for improvement (where incorrect responses were made) from returned marked scripts, if these are available, but rarely from global scores. Global scores only indicate that a learner has done well or should try to do better. However, tightly structured, interactive computer-based assessments can direct test-takers back to an easier level of performance, during an assessment, if they fail at a particular level. This is common in apps for foreign language learning.

The remarkable thing about this list is how familiar it has become. Indeed, many lay people, including the media, and some professionals and policy makers, take it for granted that these are characteristics of all good tests and assessments.

In their key text, [Pellegrino et al. \(2001\)](#) note:

Most current tests, and indeed many aspects of the science of educational measurement, have theoretical roots in the differential and behaviorist traditions. The more recent perspectives – the cognitive and situative – are not well reflected in traditional assessments but have influenced several recent innovations in the design and use of educational assessments (p. 60).

It is these alternative approaches, more congruent with cognitive and situated/sociocultural views about learning, that are discussed next.

Learning as individual sense-making, and implications for assessment

This second cluster of theories of learning also focus on the individual and the acquisition of knowledge and skill, but take a more active view of learning, recognizing that what is learned is rarely identical to what is taught. An emphasis on individual meaning making indicates a particular interest in cognition: the working of the mind as a function of the brain. Assessments, from this viewpoint, go beyond testing factual recall to tap into deeper understandings.

Cognitive constructivist views of learning

Behaviorists' denial of the importance of mental processes in learning provoked a reaction from psychologists, linguists, cognitive scientists, computer scientists and latterly, neuroscientists, who were quick to point out that human learning must, at the very least, involve thinking. All argued that learning is determined largely by what goes on in people's heads. More significantly, however, they argued that learning involves people in making sense of the world by building mental models of how the world works so that they can interpret—or make sense—of new information. Thus learning is not simply absorbing information but an active process of meaning making.

Recently, there has been much talk of personalized learning, however, according to cognitive constructivism, learning is by definition personalized because people will always make sense of their experiences in unique ways. No one person's mental models will be quite the same as those of others because they have been shaped by different prior experiences. These models provide the lenses through which we view new experiences and lead us to pay great attention to some features and perhaps ignore others. Generally this is useful because selecting phenomena, or aspects of phenomena, for our attention helps us to manage the sheer quantity of incoming sensory data. Of course, such frameworks can also blind us to the significance of new experiences—even lead us to adopt prejudiced views. In this context the task of instruction is not simply to impart information, or to provide practice for skill development, but to help learners evaluate established mental maps and adapt, extend or renew them so that they expand perception and deepen understanding.

The emphasis within this perspective is on the development of conceptual understanding, which is particularly important in the learning of academic subjects. Thus concepts, and the relationships among them, are important because these form the basis of our mental models (schema). The need to build such models is familiar in schools, from the use of spider diagrams to map topics in elementary schools, to concept mapping as a revision practice in high schools. The nodes in these diagrams are usually nouns and the links are verbs.

Such models are built using a range of mental processes. Acquiring knowledge is one such process but at a higher (or deeper) level are processes such as comprehension, application, analysis, synthesis and evaluation—categories derived from Benjamin Bloom's (1956) influential classification of cognitive objectives. The application of concepts in solving problems is particularly valued for its capacity to reveal understanding and to lead to the construction of new knowledge. Failures to solve problems can often be traced to misunderstandings of concepts or their relationships. For example, misunderstandings or misunderstanding of the nature and role of photosynthesis in plants can have profound consequences for solving problems of climate change.

The task for education, according to this view, is to help novices acquire the ways of thinking possessed by experts, notably the ways they organize knowledge so that it is more retrievable and useful. Characteristically experts solve problems more quickly, with "less search", because their models help them to know what is salient. They are also capable of reflecting upon and controlling their mental processes through the exercise of metacognitive processes—thinking about thinking.

Implications for assessment

Some of the implications for assessment practice, that flow from cognitive constructivist views of learning, are similar to those for the assessment of learning viewed as the acquisition of knowledge, but there are also significant differences in approach and emphasis. James (2008), labeled this "second generation assessment":

- The learning of the individual is assessed.
- But, the focus is on problem solving and understanding.
- Performance tends to be defined as demonstration of ability to apply conceptual frameworks to find solutions to problems, and to demonstrate cognitive skills.
- Tests and examinations are specially constructed for the purpose of assessment and are often scheduled at the end of a course or sequence of learning.
- Tasks may be extended in order to allow those being assessed to display the breadth and depth of their understanding, or to solve complex problems. Essays, concept maps, think-aloud protocols, open-ended assignments, projects, coursework or theses may be the preferred form of response.
- Assessments are, nevertheless, often time-limited, on the assumption that speed of completion of a task indicates that acquisition of conceptual models is secure and promotes understanding and problem solving with less search.
- Some limited access to materials, such as the text of novels or poetry in literature examinations, may be permitted because the assessment is less a test of memory than an assessment of understanding.
- Responses to the tasks or problems are assessed according to specified criteria which involve judgment on the part of the assessor because there will rarely be one correct answer. Judges therefore need to be trained to ensure that their assessments are in agreement with those of others. They may be given access to marking schemes or scoring rubrics, and exemplars (or model answers) for this purpose. This will probably also require the setting up of moderation or standardization procedures so that assessors, examiners or verifiers can share and discuss their judgments of a selection of work, thus developing a conception of appropriate standards in a progression from novice to expert.
- The notion of a progression often implies a ladder of scores, levels or grades based on some norm-referenced assumptions.
- Another assumption is that improvement comes from efforts to close the gap between novice and expert performance. This need not be interpreted as a linear progression but could be regarded as development toward a horizon of possibilities.
- Areas for improvement can be inferred from misunderstandings or failures to find viable solutions to problems. These may indicate flawed conceptual understanding or poor frameworks that need to be revisited, unpicked and reconstructed. This implies that certain ideas may need to be unlearned or re-learned in formative classroom processes, or that new cognitive skills need to be developed.

This approach to assessment remains focused on the acquisition and processing of knowledge, as something possessed by individuals. For this reason, some tests or examinations combine elements of both behaviorist and constructivist approaches. Examples might be tests that begin with short answer questions based on factual recall, progressing to more extended, problem-solving tasks or essay-type questions.

Pellegrino et al. (2001) provide many examples from mathematics and science of how the cognitive constructivist perspective has been incorporated into the recent design of assessments. Particular emphasis is given to ways of detecting how people organize information in schema in long term memory, how they use this knowledge to solve problems, how they develop metacognitive skills, and how they engage in communicative practices appropriate to subject domains. They advise that assessment methods can be expanded beyond traditional tests by drawing on the ways in which academic research is conducted to investigate learning; computerized systems are mentioned including intelligent tutoring, time-reaction monitoring, and simulations. However, the social dimension is largely interpreted as a context for individual learning, rather than integral and inseparable.

A third approach to assessment practice (below) makes a more radical shift—away from seeing learning as acquisition of knowledge and/or understanding to learning as participation in social practices.

Learning as building knowledge through social interaction, and implications for assessment

A third view of learning is often called the sociocultural, or situated. It is sometimes regarded as a new development. However, [Bredo \(1997\)](#) traces its intellectual origins back to the work of William James, John Dewey and George Herbert Mead at the beginning of the twentieth century. Its origins therefore pre-date both behaviorism and cognitive constructivism.

Sociocultural/situated views of learning

A key principle of sociocultural theory is that learning involves both thought and action in context and is particularly influenced by the interactions among these phenomena. This may explain why it is often seen as more complex than behaviorism, which concentrates on behavior, or cognitivism that focuses on thought processes. The interactionist approach of Dewey and Mead viewed human development as a transaction between the individual and the environment, between actor and structure. This had something in common with the development of cultural psychology in Russia, associated with [Vygotsky \(1978\)](#), who was himself influenced by William James, and possibly met Dewey. This transatlantic conversation continued as Vygotsky's thinking subsequently influenced theorists such as [Bruner \(1996\)](#) in the US and [Engeström \(1999\)](#) in Finland. Other key theorists who regard individual learning as situated in the social environment include Barbara [Rogoff \(1990\)](#), Jean Lave and Etienne Wenger ([Lave and Wenger, 1991](#); [Wenger, 1998](#)) who draw on anthropological work to characterize learning as cognitive apprenticeship in communities of practice.

According to this perspective, thinking is conducted through actions that alter the situation and the situation changes the thinking; the two constantly interact. Especially important is the notion that learning is a mediated activity in which cultural tools and artifacts have a crucial role. These can be physical artifacts such as books and equipment but they can be symbolic tools such as language and sign systems. Since language, which is central to our capacity to think, is developed in relationships between people, social relationships are necessary for learning. Learning is by definition a social and collaborative activity in which people build knowledge and develop thinking together.

Learning involves participation and what is learned is not the property of an individual but distributed within the social group. For example, an ability to use language skills is not solely an indication of individual intelligence but of the intelligence of the community that developed the language, which the individual then puts to use. The collective knowledge of the community is internalized by the individual. Similarly, as an individual creates new knowledge, for example, a new way of using a tool, then he or she will externalize that knowledge in communicating it to others who will put it to use and then internalize it. In this way, knowledge is created and shared in expansive learning cycles.

These ideas have implications for instruction. They imply that the teacher needs to create an environment in which people can be stimulated to think and act in authentic tasks, like apprentices, beyond their current level of competence, but in what Vygotsky calls their zone of proximal development, see below. Access to, and use of, an appropriate range of tools is an important aspect of such an expansive learning environment. It is important to find activities that a learner can complete with assistance but not alone so that the more expert other, in some cases the teacher but often a peer, can scaffold their learning and remove the scaffold when they can cope on their own. Tasks need to be collaborative and students need to be involved both in the generation of problems and of solutions. Teachers and students become a community and jointly solve problems, so all develop their skill and understanding.

According to this view, the most valued outcomes of learning are therefore engaged participation in ways that others in the community of practice find beneficial. It follows that it is problematic to judge an individual as having acquired knowledge in general terms, abstracted from action settings.

Implications for assessment

These sociocultural theories provide powerful descriptions and explanations of learning but their implications for assessment, especially in school contexts, have not been fully worked out. This is not really surprising because the key theorists have focused on learning, rather than assessment. However, if assessment is to be aligned with learning then appropriate linkages need to be found. The pointers that follow are therefore somewhat speculative. [James \(2008\)](#), labeled these "third generation assessment":

- If learning cannot be separated from the actions in which it is embodied, then assessment too must be situated. This implies that assessment is carried out alongside learning, not after learning.
- Assessment alongside learning implies that it needs to be done by the community rather than by external assessors. There is a role for self-assessment, peer-assessment and teacher assessment.
- Assessment of group learning is as important as the learning of the individual.
- "In vivo" studies of complex, situated problem solving are the most appropriate form for assessments to take because learning is expressed in participation in authentic, real-world activities or projects.
- The focus is on how well people exercise agency in their use of the resources or tools (intellectual, human, material) available to them to formulate problems, work productively and evaluate their efforts. This is a proper justification for coursework assignments and encourages access to source materials because it is the ways in which these are used that is of most significance.
- Learning outcomes can be captured and reported through various forms of recording, including narrative accounts and audio and visual media.

- The portfolio has an important role because it has the potential to capture assessment as inquiry. However, attempts to grade portfolios according to scoring rubrics, as has happened in the USA, is out of alignment with the sociocultural perspective because it reduces the possibilities to assessment as procedure or even assessment as measurement (Serafini, 2000).
- Judgment needs to be holistic and qualitative, to be consistent with a sociocultural or situated approach, not atomized and quantified as in measurement approaches.

This list of characteristics points to possibilities for forms of assessment in sympathy with valued instruction and learning practices in schools, colleges and workplaces. It is especially suited to the assessment of collaborative group work on extended projects. This could make it especially attractive to employers who increasingly claim they are interested in recruits who can demonstrate their capability to work in teams to find creative solutions to complex problems. However, it raises a number of questions about how progression is conceptualized and recognized, and how achievements can be generalized in trustworthy ways when large numbers of students are involved and when those who are interested in the outcomes of such learning cannot participate in the activities that generate them.

Issues of progression and generalizability in sociocultural approaches

The following discussion is also tentative because these issues have not been resolved. It draws substantially on discussions in James (2010, 2017).

On progression, Vygotsky and his followers have something interesting to say.

The structures of grades, scales and attainment levels have accustomed us to regard progression as step-by-step and linear. According to Vygotsky, the mastery of tools of the mind takes place in the zone of proximal development (ZPD). As Grigorenko (1998, p. 210) points out:

The word 'zone' refers to the nonlinearity of children's development. In this zone, the child might move forward or backward, to the left or to the right. ... The main characteristic of the ZPD is its sensitivity to the child's individuality – its responsiveness to the unique profile of each child's skills.

The point to be made here is the value in plotting learners' development as a profile within a zone and encouraging them to expand, deepen and enrich their knowledge, skills and understanding.

Vygotsky's view that what learners can do at lower levels should not limit opportunities for their development of higher functions was almost certainly influenced by his experience of working at a boarding school for children who were both deaf and blind. He claimed that education targeted on the formation of higher mental processes could help people overcome, or compensate for, deficits because it equipped them with adaptive strategies that might be unique for each person.

Although sociocultural approaches can make claims for greater authenticity and validity, they are a long way from providing convincing assurances about the dependability of assessment results. A particular challenge is the question of whether, within a sociocultural theoretical framework, it is possible to make generalizations about a learner's mastery beyond the specific context of the assessment, however extended and rich this assessment activity might be. Baird et al. (2017) point out that psychometricians design assessments with multiple items to sample the domain of interest in representative ways using the now sophisticated statistical techniques available to them. These approaches command respect and generate confidence although there is a tendency for much of the debate surrounding them to shift to technical issues of measurement, such as the strength of correlations among items designed to represent constructs. The nature of the constructs themselves is sometimes scrutinized less well, e.g., what constitutes "reading". The danger is that the items can come to define the construct, rather than the other way round, with the consequence that teachers feel pressured to teach their students how to answer test items, which become the de facto curriculum.

A sociocultural approach, in which rich assessment tasks are integrated with the curriculum in such a way that they can be valued as learning tasks themselves, might be a solution to this problem. The act of generalization could then become integral to the assessment task if it draws together many relevant parts of the domain, which may be multidisciplinary, and requires students to demonstrate, evaluate and apply their accumulated knowledge and skill to a substantial problem. An example, of this approach in schools might be the "exit exhibitions" promoted by the US Coalition of Essential Schools founded bySizer (1992). In post-graduate higher education, mastery of the chosen field is demonstrated in the doctoral thesis or dissertation with oral examination. In craft training, in the past, the "masterpiece" was the piece of work designed to demonstrate the highest levels of expertise of the apprentice or journeyman wishing to become a member of the guild. In all these cases, the basic premise is that an individual who is capable of identifying and organizing the knowledge salient to the problem, and devising, executing, and communicating a solution which is judged worthy by more expert others, is judged to have mastered the more general field at the required level. In all these contexts, mastery is the key concept.

The roots of all these assessment practices predate psychometrics by several centuries. However, the confidence placed in them depends on the strength of the arrangements for fairly judging performances and outcomes. A justified concern is that judgment can be biased by prejudice, favoritism, nepotism or corruption. These are extreme examples but the danger of unwitting bias when teachers are assessors of their own students is real (Bennett, 2011). The strength of psychometric methods of assessment is that they have effective tools for detecting bias and strengthening the reliability and generalizability of inferences drawn from results. These tools cannot easily be used within sociocultural approaches that promote the use of authentic assessment tasks, the outcomes of which cannot be wholly pre-specified. However, efforts to eliminate bias, to ground judgment securely in evidence, and to draw

conclusions about mastery that have more general applicability are crucial. These challenges might be met by using established ethnographic methods for assuring quality of inferences from evidence. Among these, triangulation and reflexivity are especially important. Reflexivity requires assessors to think very carefully about why their judgments might be wrong and actively seek evidence that might, in Popperian terms, falsify them. Triangulation can be achieved both by comparing different pieces of evidence of mastery, e.g., in the judging of a portfolio of work or exhibition as is characteristic of visual and performing arts courses, and by making arrangements for more than one assessor to judge performances and outcomes with a view to coming to an agreement on quality. Systems of moderation are examples of this.

High quality teacher moderation has been developed for large-scale assessment (Maxwell, 2010) although generally such systems are regarded as costly in terms of money and time. Nevertheless, apprenticeship models, from which some sociocultural ideas derive, may offer solutions because underpinning such models is the concept of the community of practice that is the guardian and arbiter of developing standards. In other words, validation of standards by a community of experts, or, at least, “more expert others”, may be a way of assuring quality. This raises a question, however, of whether assessors or judges should work from standard sets of criteria (rubrics) to form generalizable judgments, or whether it is more appropriate, in the context of assessing authentic tasks, to work back from expert judgment to the criteria of quality that inform them. Lawrence Stenhouse, who was opposed to the objectives model of curriculum development, argued that complex performances can be critically evaluated but not pre-specified (Stenhouse and Verma, 1980; see also James, 2012b).

More work could be done to develop assessments that are coherent with sociocultural perspectives on learning, and to find solutions to evident problems. It is not necessary to displace psychometric approaches entirely, but it may be important to find ways to complement them in order to provide more complete accounts and evaluations of learning and achievement.

Can different approaches to learning and assessment be combined? The importance of curriculum

The previous sections have attempted to show what congruence between assessment practice and beliefs about learning might look like. If assessment practice is out of line, effective learning can be undermined because assessment wash back is so powerful, especially in high stakes settings. A key question for teachers, trainers and assessors, is whether they can blend approaches or whether they need to adopt a particular approach, to the exclusion of others. Theoreticians often take the view that theories should take adequate account of all relevant phenomena to provide as complete a solution as possible. However, principled and pragmatic compromises can be reached. The overarching principle is fitness for purpose: always a key criterion for choice of assessments.

The nature of the subject domain might encourage one approach in preference to another. For example, science and mathematics, with hierarchically ordered conceptual structures may lend themselves to constructivist approaches better than broader fields of study, such as the expressive arts, with contested or multiple criteria of what counts as quality learning. The latter may sit better with sociocultural approaches that value context, process and community. However, it would be wrong to claim that the relationship between particular subject domains and particular learning theories, and their associated assessment practices, are exclusive. Almost every subject domain has a number of different aspects that might require different approaches. Take reading and writing in mother tongue for example. In terms of functional literacy, a behaviorist approach might be adequate, but when it comes to understanding and interpreting text, in terms of concepts such as plot, character, setting and metaphor, a cognitive constructivist approach may be needed. Creative writing will demand something different again. Novice writers will need to learn how to develop expertise in a community of practice (see James, 2006, for a developed example). This implies that it is important to scrutinize the variety of curriculum aims and/or desired outcomes within a subject domain, or field of study, before adopting a particular approach to learning, instruction and assessment.

A grounded analysis by James and Brown (2005) of 30 projects in the UK's Teaching and Learning Research Program (2000–2011) identified seven categories of valued outcomes. None were exclusive to any particular subject domain or education sector.

- *Attainments*—often implying mastery of information, facts, specific rules or mental procedures associated with particular tasks. They are frequently assessed in traditional ways through tests and examinations.
- *Understanding*—of ideas, concepts, processes. These imply more abstract, conceptual ways of thinking and the capability to make reasoned judgments about meanings and inference.
- *Cognitive and creative*—imaginative construction of meaning, arts or performance. These focus on the capability to create or discover new knowledge, whether personal, cognitive, esthetic or practical.
- *Using*—how to practice, manipulate, behave, engage in process or systems. This implies the development of known practical and technological skills and being able to apply them in appropriate contexts.
- *Higher order learning*—advanced thinking, reasoning, metacognition. These concepts of learning transcend other learning outcomes. They place emphasis on more sophisticated overarching cognitive processes.
- *Dispositions*—attitudes, perceptions, motivations. These reflect the affective conditions within learners that are assumed to be necessary to effective learning in specific contexts.
- *Membership, inclusion, self-worth*—the learners' affinity toward, readiness to participate in, and sense of worthwhile contribution to, the group where the learning takes place. It is concerned with establishing social and substantive identities.

The first question to ask is, what curriculum aims and outcomes are we seeking to achieve? Then we can ask, what approaches to learning and assessment are most appropriate?

There is also evidence that learning theory is shifting from former paradigmatic stances. Many cognitive constructivists have taken on board the importance of the social dimension of learning: hence the increasing use of the term “social constructivism”. And sociocultural researchers are involved in a “discursive shift” to recognize the cognitive potential in explaining how we learn new practices (Edwards, 2005). This suggests possibilities for synthesis whereby a more complete theory can emerge from blending and bonding of key elements of previous theories. Such synthesis may lead to a new alignment. The possibility for a more complete and inclusive theory of learning to guide practice and assessment seems to be a goal worth pursuing.

Learning (how) to learn and implications for assessment

The importance of “learning to learn”, or “learning how to learn”, has been claimed for a long time but more recently because it is felt to be especially important for lifelong learning in the 21st century. The crucial resource is thought to be the ability of people to respond flexibly and creatively to demands for new knowledge, skills and dispositions in continuously changing environmental, social and economic contexts, especially in a digitally networked world. In the first decade of the 21st century, a number of projects and initiatives sought to elaborate the concept and to investigate the roles that assessment might have. Many of these initiatives were generated in Europe although Learning to Learn was also the title chosen by Hong Kong for its holistic reform of curriculum and assessment in the same decade (James, 2021).

In 2006, the European Parliament and Education Council defined the concept learning to learn as:

Learning to learn is the ability to pursue and persist in learning, to organize one's own learning, including through effective management of time and information, both individually and in groups. This competence includes awareness of one's learning process and needs, identifying available opportunities, and the ability to overcome obstacles in order to learn successfully. This competence means gaining, processing and assimilating new knowledge and skill as well as seeking and making use of guidance. Learning to learn engages learners to build on prior learning and life experiences in order to use and apply knowledge and skills in a variety of contexts: at home, at work, in education and training. Motivation and confidence are crucial to an individual's competence.

European Union Education Council (2006, para. 5, annex).

This definition attempts to avoid reducing the concept to study skills that can be taught, learned and assessed, often as a separate course or program, in the hope and expectation that they will then be applied to learning in the formal curriculum. It also attempts to embrace the range of perspectives on learning that an expert group of researchers and stakeholders brought to the discussions that informed the Council in 2005. The intention was to produce an indicator system that might be used across countries and regions for mainly diagnostic purposes i.e. to identify areas for intervention. A suite of measures of learning to learn capability, drawing mainly on scales previously developed at the Universities of Helsinki and Bristol were proposed as a pilot in eight countries. It is difficult to find evidence of the outcomes of this initiative. It seems that, in the end, the European Union decided to accept the non-content specific measures, such as problem-solving, in the OECD's Program for International Student Assessment (PISA), as a proxy for learning to learn in Europe.

The whole field of learning (how) to learn research and scholarship is too vast to deal with adequately here. For the purposes of this chapter, and in light of the discussion in previous sections, the most pertinent feature is the extent to which the debate is framed in terms of learning theories. The report from the European Commission Joint Research Center (Hoskins and Fredriksson, 2008), on the deliberations of the expert group, has a section on the paradigm debates. Most of the projects examined for helpful insights claimed that they drew on both cognitivist and sociocultural theories, although their work had different emphases that indicated different approaches in practice. Three examples illustrate this. All were represented on the European Commission's expert group.

The University of Helsinki projects (Hautamäki, 2014) acknowledge the influence of both Piaget and Vygotsky in the development, begun in 1996, of a set of scales to assess learning to learn (LTL) capability. This is defined as cognitive competences and the attitudes and beliefs that support the effective use of them. These skills are assessed by pencil-and-paper or computer-based group tests comprised of cognitive tasks and self-report questionnaires. The cognitive component is measured by tasks that are related to curricular content but they require the application of “higher-order” thinking skills. Thus the Finnish LTL scales cover reading comprehension, mathematical thinking skills and more general thinking and reasoning skills, including problem solving. They were developed by psychologists, behavioral scientists and psychometricians and were designed to assess, in cross-sectional and longitudinal studies, the effectiveness of education at system level. They were to provide evidence-informed explanations of how differences between groups of students, classes, schools, districts and countries develop and what kinds of factors are related to different trajectories of development. For all these reasons the scales were of particular interest to the European Commission in its hope of developing a learning to learn indicator for use in member countries. The Helsinki tools were not designed to be diagnostic at individual level; however, the focus has been shifting toward the use of assessment results in the development of classroom practices (Vainikainen, 2014).

The University of Bristol project has similarities but also marked differences. The metaphor of learning as a journey is implicit in Helsinki's developmental approach but it is quite explicit in the work at Bristol. Moreover their definition of learning how to learn “involves the person who is learning, and requires motivation, a sense of direction and desire, and a sense of agency and self-regulation” (Deakin Crick, 2007, p. 138). Thus the focus is on attitudes, values and dispositions and what the Bristol team call

“learning power”. This refers to seven core dimensions of the capacity to learn how to learn, which emerged from a factor analytic study of nearly two thousand learners (Deakin Crick et al., 2004). These factors are: changing and learning; critical curiosity; meaning making; dependence and fragility; creativity; relationships/interdependence; strategic awareness. This analysis gave rise to the design of a self-report 72-item questionnaire—the Effective Lifelong Learning Inventory (ELLI). This elicits information from the learner about how they report themselves on each of these dimensions at a particular point in time. The results can be fed back to the individual learner in profiles represented as spider diagrams, or aggregated for classes and schools in pie charts.

The ELLI learning profile is described by its authors, as a form of dynamic assessment with an interactionist (sociocultural) orientation. According to Deakin Crick (2007, p. 150)

The dynamic assessment of students’ learning power serves a number of pedagogical purposes. First, it reflects back to the learner what they say about themselves in relation to their personal power to learn. Second, it reflects back to the teacher data about individuals, and groups, which can be used for diagnosing what is needed to move forward in the development of self-awareness, ownership and responsibility for learning. Third, the dimensions of learning power provide scaffolding for the ways in which students encounter the formal content of the curriculum. All of these operate together

Deakin Crick et al. (2015) later reanalyzed 15 years of data from ELLI and concluded that a more parsimonious and robust model was possible. This analysis examined the relationships among the previous dimensions of learning power and identified the overarching importance of developing resilient agency in learning—an embodied and relational process. This locates it firmly with a sociocultural frame.

Whereas the Helsinki scales were first designed to be assessments “of” learning to learn, the Bristol inventory was intentionally assessments “for” learning to learn. However, because both projects produced diagnostic assessment instruments they are open to both summative and formative uses.

The Cambridge based project (James et al., 2007), which also involved researchers from King’s College London, the Open University and Reading University, had a very different focus, although within a sociocultural theoretical approach. This project chose the phrase “learning how to learn” (LHTL) in order to draw attention to the development of learning practices. This focus was consistent with the project’s starting point in assessment for learning: a label for a group of formative practices that had been shown to help learners to improve learning and achievement (Black and William, 1998). Four clusters of classroom practices were thought to be particularly important:

- helping learners to understand learning aims and objectives and what counts as high-quality learning;
- helping learners to build on strengths and overcome barriers in their previous learning;
- helping learners to know how to act on constructive feedback and how to develop the motivation to do so;
- helping learners to use the help of others, including through peer-assessment, to enhance their understanding and take responsibility for their learning.

The central aims of the project were to investigate what teachers can do to help students to learn how to learn, and to investigate how this can be supported and managed in schools and across networks, including electronic networks. A suite of tools was developed (James et al., 2006) but these tools are mostly in the form of professional development activities. However, they include a survey instrument for investigating teachers values and practices, which was a key instrument used in the research.

As in Helsinki and Bristol, clarification of the concept of learning how to learn was a first project task (Black et al., 2006). The Cambridge/King’s/OU/Reading team was multidisciplinary and they explored philosophy as well as psychology for definitions. They noted that, as early as 1976, Robert Dearden, a philosopher of education, put forward the idea that:

Learning how to learn is at one stage further removed from any direct specific content of learning. It might therefore reasonably be called ‘second-order learning’. There could be many such comparably second-order activities, such as deliberating how to deliberate, investigating how to investigate, thinking out how to think things out, and so on.

Dearden (1976, p 70).

However, this begs the question of what should be given priority in the whole range of potential second-order learning. Dearden’s leading candidate is promoting learning autonomy. The project came to regard this as the principal aim or goal of the activity of LHTL, which is promoted by assessment for learning (AFL) practices. The Cambridge project concluded that what is needed is that these ways of thinking and practicing, principally “making learning explicit” and “promoting learning autonomy”, which emerged from a factor analysis of the teachers’ survey, should permeate the whole curriculum and be integrated into every subject, and most lessons, so that students have opportunities to reflect critically and constructively on their learning while they are engaged in learning curriculum content. This approach acknowledges that there might well be different LHTL practices across the various subjects of the curriculum. It is unlikely, therefore, to be a unitary and wholly generalizable cognitive or affective competence.

This project also came to the view that it is important not to see learning only in terms of individual minds, but also to recognize the importance of the social element in learning. Even such processes as metacognition and self-regulation are developed through discourse, social interaction and collaborative activities. Adult support serves to mediate such metacognition, hence the focus in this project on working with teachers and schools to develop and support classroom practice.

As a consequence of this emphasis on LHTL practices integrated into the formal curriculum and mediated by others, the Cambridge project did not develop a measure to assess LHTL competence, although it did research LHTL practice through surveys, interviews and classroom observations. The success of these practices was assessed by the extent to which they appeared to have an impact on first-order learning i.e., learning of formal curriculum content in subject areas as measured by national tests and examinations.

The Helsinki researchers were also interested in the associations between patterns of results from their instruments and achievements as measured by assessments such as PISA. It was thought that the former might be explanatory of the latter.

Two points arise from these three projects. First, all appear to combine cognitivist and sociocultural perspectives on learning although each places more weight on one than the other. Secondly, they differ in the extent to which they focus on assessment “of” learning to learn (through the development of measurements) or on assessment “for” learning to learn (through the development of classroom practices). However, all have a diagnostic aspect, and the tools they each develop can be, and in some cases have been, used for both formative and summative purposes. According to Harlen and James (1997) what unifies formative and summative assessment processes is the extent to which they serve shared aims, goals and criteria for evaluating outcomes, whether these are framed in terms of powerful knowledge in subject domains (first-order learning) or the clusters of competences and practices termed learning (how) to learn (second-order learning).

This last observation reflects the claim made at the beginning of this chapter: that assessment needs to be congruent with our understandings about learning and that both need to be aligned with the educational aims and purposes that are valued and promoted. Therefore clarity about all these elements, and their relationships, is important.

Introduction

The assessment considered in this article focuses on and directly supports student learning rather than, for example, assessment that prioritizes qualification and accountability. Words and phrases can carry multiple meanings, and may be variously interpreted by different people. We use the term “assessment for learning” (AfL) intentionally, and set out our understanding of the concept below, for as Paul Newton urged, “To avoid getting ourselves confused, and to avoid confusing others, we need to use the language of assessment with greater precision” (Newton, 2007, p. 157). Semantics and conceptualizations make a difference to individual, collective, political, and societal understanding, discourse, and policy—and most importantly for students, for practice. Aiming for clarity is particularly pertinent in an international encyclopedia that seeks to reach across countries, cultures and languages.

The article falls into two main parts. Firstly, a decade on from the publication of the article “Getting to the heart of authentic assessment for learning” (Swaffield, 2011) we revisit arguments therein, examine points made by citing authors who have engaged with the issues, and refer to other relevant publications. This is a manifestation of the intellectual dialog that the author invited (Swaffield, 2011, p. 434). It was anticipated that such work might result in future development or change in thinking; the exercise has led to what is essentially a reaffirmation of her 2011 position, as well as a re-emphasis of key points and further clarifications.

The conceptual discussion of part 1 begins with brief considerations of assessment and of learning (both within educational contexts and particularly as relevant to AfL), as a prelude to the substantial discussion of assessment for learning, particularly as related to learning and including distinguishing AfL from formative assessment. In this first part of the article we draw on literature predominantly from Europe, North America, Australia and New Zealand.

The second part further extends the international scope of the article by focusing on AfL and learning in East Asian heritage cultures. Research across Asia has shown the importance of cultural change for successful assessment reform (Cagasan et al.,

2020; Leong et al., 2018; Wicking, 2020). We discuss AfL practice in the context of East Asian classrooms, specifically in Vietnam, Japan, Taiwan, Singapore, Brunei and the Philippines. We explore tensions and conflicts between the principles of AfL and the developmental trends that affect learner dispositions across these countries, cultures and languages.

Assessment

As is clear from other articles in this volume educational assessment is a multi-faceted concept that can be thought about in many different ways, for example: its purpose, function and use; timescale, participants, focus and scope; method and instrumentation; impact, outcome and consequence. Assessment involves evidence, interpretation and judgment. Many of these elements are key to the discussion of AfL below. The etymological root of “assessment” in the Latin word “assidere,” meaning “to sit beside,” resonates closely with the practices we understand as AfL and that are embedded in the on-going everyday dynamic of teaching and learning.

This integration and the range of practices (such as feedback) associated with AfL have led some (e.g., Brown, 2019) to suggest that what is being referred to should just be regarded as part of good teaching, and that AfL should not be termed “assessment” at all. To do this though would imply that assessment refers only to approaches such as testing and examinations for grading, selection and accreditation. The principle “Assessment for learning should be recognized as central to classroom practice” (ARG, 2002, p. 2) reflects the fact that every day learners demonstrate their knowledge, understanding and skills - evidence that is noted and interpreted as the basis for decision-making. Similarly Dylan Wiliam (2011a, p. 11) argued that “The value of using the term assessment in phrases like assessment for learning and formative assessment is that it is illuminating to draw attention to the fact that the processes under consideration can be thought of as assessment processes.” Indeed, a teacher in the course of a lesson eliciting evidence by asking questions, interpreting the responses, and making decisions about the next question or activity, is undoubtedly assessing. Our view is that this should be recognized and named as such, thus reinforcing the understanding that assessment is a broad concept encompassing much more than testing.

Acknowledging AfL as assessment also highlights the important role of students in assessment. Rick Stiggins, reflecting on his own learning about classroom assessment from Anne Davies and Ruth Sutton, highlighted “the power of student involvement in the ongoing classroom assessment process as a way to develop in students a sense of control over their academic well-being—to help them maintain the confidence that success is within reach if they keep striving” (Stiggins, 2016, p. vi). Self-assessment and peer support are central to students’ autonomous regulation of their learning.

Learning

Learning, like assessment, is a concept with multiple meanings and interpretations, and that is also explored in depth in other articles in this volume, notably Mary James’ (2023). Drawing on earlier work (e.g., James, 2008) she examines relationships between processes of assessing and processes of learning, demonstrating that different theories of learning have various implications for assessment. She identifies and discusses three views of learning using Chris Watkins’ (2003) framing (learning as acquiring what is taught; learning as individual sense-making; and learning as building knowledge through social interaction), incorporates Anna Sfard’s (1998) two metaphors for learning of acquisition and participation, and matches them to underlying theories (behaviorist; cognitive constructivist; and sociocultural). Key points that are particularly relevant for this discussion of AfL are that: (1) assessment practices appropriate for behaviorist views of learning prevail, and many people regard them as good assessment per se; (2) cognitive constructivist perspectives, while also focusing on individuals’ knowledge acquisition and processing, might additionally involve problem-solving; and (3) sociocultural learning theories suggest collaborative group work on extended projects, but the assessment of such practices has yet to be fully developed, and the issues arising (such as the trustworthy attribution of achievement and the recognition of progression) resolved. James argues that relationships between learning theories, assessment practices and indeed subject domains, are not exclusive, and stresses the overarching principle that assessment must be fit for purpose. Her final section considers learning (how) to learn through three projects including the four-university Learning How to Learn (LHTL) project that she led (James et al., 2007). All three projects combined cognitivist and sociocultural perspectives. The LHTL project was particularly related to AfL, and will be returned to later.

In the previous edition of this encyclopedia Paul Black (2010) offered another perspective on learning particularly relevant to AfL. He summarized “established principles for effective learning” as:

- “Start from a learner’s existing understanding
- Involve the learner actively in the learning process
- Develop the learner’s understanding of the aims and criteria for effective learning
- Promote social learning i.e., learning through discussion”. Black (2010, pp. 361–362).

Black pointed out that while these principles concern cognitive dimensions of learning, Ruth Butler (1988) and Carol Dweck (2000) have highlighted the importance of affective and motivational dimensions. Their work underpins other principles about learning especially concerning the nature and focus of feedback, advocating sensitive and constructive comments that relate to the progress and achievement of the task and how to improve still further. All these points are also germane to the discussion of AfL below.

Assessment for learning

History

Our understanding of AfL is informed by research published predominantly since 1998, along with important antecedents. The early history and underpinnings of AfL have been detailed elsewhere (e.g., [Swaffield, 2011](#); [Wiliam, 2011a,b](#); [Baird et al., 2017](#)); of significant note are:

1967 Michael Scriven's coining of the term "formative evaluation"

1969 Benjamin Bloom describing brief classroom tests to aid learning as formative evaluation

1984 England's and Wales' statement of policy for Records of Achievement

1986 Lynn Fuchs' and Douglas Fuchs' review of the effects of formative evaluation

1986 Harry Black's coining of the term "assessment for learning"

1987 Gary Natriello's review of the effect of evaluation on students

1988 Terence Crook's review of the impact of classroom practices on students

1992 Mary James' conference paper entitled "Assessment for learning"

1995 Ruth Sutton's book entitled "Assessment for Learning"

1998 Paul Black's and Dylan Wiliam's review of classroom formative assessment.

[Black and Wiliam's \(1998a\)](#) review has been enormously influential and spawned a huge increase of activity in the field, encompassing research, practice and policy. Its impact was probably due not only to the finding that substantial learning gains are possible, but also to a number of other factors. The review had been commissioned by a group of UK academics, called the Assessment Reform Group (ARG), who continued to support and advance the work. The review's main findings were widely disseminated: alongside their journal article the authors wrote a summary ([Black and Wiliam, 1998b](#)) that rapidly sold tens of thousands of copies. This was the first of a number of A5 sized pamphlets published by King's College London (the "Inside the black box" series) and by the University of Cambridge (e.g., [ARG, 1999](#)) making academic research on AfL accessible by distilling key messages for teachers, school leaders, advisers/consultants and policy makers. In England AAIA (The Association for Assessment Inspectors and Advisers, later renamed the Association for Achievement and Improvement through Assessment) worked closely with teachers and school leaders to develop AfL practice. ARG members were active and influential throughout the UK and beyond, while in 2001 Sutton and Stiggins initiated what was to become a series of international symposia [2001 Chester, UK; 2005 Portland, USA; 2009 Dunedin, New Zealand; 2011 Bergen and Solstrand, Norway; 2014 Fredericton, Canada; 2016 Brisbane, Australia] and a network moving the field forward (see [Laveault and Allal, 2016](#)).

Of the many empirical research projects that built on Black and Wiliam's review, two were directly related and are noteworthy. The King's Medway Oxfordshire Formative Assessment Project (KMOFAP) involved Black, Wiliam and colleagues working closely with 48 teachers from six senior-age schools. Together they explored the translation of ideas from the 1998 review into classroom practice ([Black et al., 2002, 2003](#)). These teaching and learning approaches were also found to improve test and examination results ([Wiliam et al., 2004](#)). The teachers' commitment, creativity and professional realism generated many effective and contextualized teaching and learning activities. The collaborative process of knowledge creation was also the basis for the researchers' wider

theorization about putting AfL into practice including the centrality of teachers' attitudes and beliefs, school leadership and professional learning.

The other closely related research was the Learning How To Learn project previously mentioned (James et al., 2007). It was another development and research project, though much more "light touch" in terms of intervention, and much larger in scope and size, than KMOFAP. LHTL involved researchers from four universities including members of the KMOFAP team, 40 schools, and approximately 1500 teachers. Using AfL as a starting point the project investigated how LHTL could be promoted in classrooms, schools and networks. One of the many research tools was a questionnaire that investigated teachers' classroom practices and values revealing salient factors later framed as principles.

Alongside and complementing funded research projects, many proponents of AfL have extensive and long-term engagement with practitioners, directly developing teachers' skills and understanding while growing the knowledge base through analysis and publication. Particularly prominent either side of the north Atlantic are Shirley Clarke, Dylan Wiliam, and Anne Davies and colleagues.

Definitions and key characteristics

Sue Swaffield (2011) discussed two definitions of AfL, both developed by experts in the field through extended dialog drawing on research. The first:

Assessment for Learning is the process of seeking and interpreting evidence for use by learners and their teachers to decide where the learners are in their learning, where they need to go and how best to get there.

ARG (2002, pp. 2–3).

was widely adopted and continues to be used with fidelity. However, its misinterpretation by some policy makers and practitioners as frequent use of summative tests led to the 31 attendees at the third international symposium drawing up a position paper on AfL (Klenowski, 2009). Central to this statement was a revised definition, coherent with and complementing the ARG's (2002) definition, to make clear the central focus on learning by students...

Assessment for Learning is part of everyday practice by students, teachers and peers that seeks, reflects upon and responds to information from dialogue, demonstration and observation in ways that enhance ongoing learning."

Klenowski (2009, p. 264). line breaks added to the original.

The accompanying commentary elaborated each of the five phrases (emphasized by layout above) to elucidate the definition. These two key definitions of AfL, together with their originators' arguments and discussion by other authors, portray practice with a number of features that are fundamental characteristics of our understanding of AfL. Students are the supreme focus; their learning is the primary aim of AfL, and their active participation essential.

Student agency

Centrally and crucially, students are key actors in AfL. As Stiggins (2002, p. 761) asserted "assessment for learning must involve students in the process." The importance of active student involvement in assessment has long been recognized (for example DES/Welsh Office, 1984; Broadfoot, 1986; Sutton, 1992, 1995; Perrenoud, 1998), and for much longer and even more internationally in relation to learning in general (for example Confucius, Socrates, John Dewey, Maria Montessori, A.S. Neill, and Lev Vygotsky). Early exponents of AfL practice, notable Ruth Sutton (1992, 1995) and Shirley Clarke (1998) from England, and Anne Davies (2020) from Canada, learned the criticality of student involvement through personal experiences in their own classrooms and with other teachers. Research strengthened their convictions.

Students can be actively involved in their learning in many ways, and it is their self-regulation that is essential to the discussion here. Christian Brandmo et al. (2020) (drawing on Schunk and Greene, 2018) describe self-regulated learning (SRL) as "the process where the learner activates and sustains their cognition, motivation, behaviors and feelings toward the attainment of a learning goal" (Brandmo et al., 2020, p. 332). This quotation is from their editorial for a journal special issue on "Bridging classroom assessment and self-regulated learning" (Assessment in Education: Principles, Policy & Practice, Volume 27 Number 4). The authors of the articles in the special issue drew on rich and diverse backgrounds to make substantial conceptual contributions (notably Allal, 2020; Andrade and Brookhart, 2020; Chen and Bonner, 2020; Greene, 2020), and reported empirical studies.

Linda Allal's (2020) model is actually of the over-arching concept of co-regulation (following Perrenoud, 1998), which has self-regulation at its core, nested within peer interaction, teacher interventions and interactions with students, all encompassed by the regulating structure of the teaching/learning situation. At each layer a range of "tools" (including specific assessment procedures and instruments) is operating. The different levels of regulation are interconnected, therefore tools need to be designed, used and

understood coherently. For example, for a student to learn from feedback (from whatever source) time needs to be built in for the feedback to be considered and acted upon, and—as Ron Berger’s (2003) work so powerfully illustrates—a culture to have been created in which feedback is regarded as positively helpful rather than a label or determinant of potential. Heidi Andrade and Brookhart (2020) also take a co-regulation perspective on classroom assessment, and their organizing framework (built on Pintrich and Zusho, 2002) for self- and co-regulation of learning considers four phases (spanning forethought to reflection) and four areas of learning including cognition and affect. Their work “suggests that classroom assessment plays a vital role in the regulation of learning, as well as the converse: the regulation of learning requires assessment evidence” (Andrade and Brookhart, 2020, p. 366). This iterative process is also evident in a third framework (Chen and Bonner, 2020)—developed from Barry Zimmerman’s (2002) cyclical model of SRL—that emphasizes students as active agents at all stages of classroom assessment/self-regulated learning.

Self- and co-regulation of learning are predicated on a number of other key characteristics of AfL. These relate to the what, how, when, where and who of AfL, and all involve students as active participants.

Focus on learning

“The primary aim of Assessment for Learning (AfL) is to contribute to learning itself” (Klenowski, 2009, p. 263)—in contrast to focusing directly on test performance. The 2009 position paper went on to explain the logic of that assertion: “when true learning has occurred, it will manifest itself in performance. The converse does not hold: mere performance on a test does not necessarily mean that learning has occurred” (Klenowski, 2009, p. 263). As Manu Kapur (2016, p. 289) argues “Learning and performance are not always commensurable. Conditions that maximize performance in the initial learning may not maximize learning in the longer term.”

As part of everyday practice (that includes the development of good learning habits) AfL is concerned with progress on specific short-term learning intentions. Cumulatively these curriculum outcomes contribute to the attainment of long term learning goals that are often expressed as standards expected by the end of one or more years of study. It is only fairly recently (corresponding approximately with the development of AfL practices, and in England with the introduction of a national curriculum from 1988) that it has become common practice to share with students what they should be learning and not just what they should be doing. The importance of doing so was demonstrated by John Frederiksen and White (1997) in one of the eight cornerstone examples of research used by Black and Wiliam (1998a): put simply, students improve more when they understand what is required. Learning intentions and their associated success criteria (Clarke, 2005, 2014) can and should take different forms including in their degree of openness. Tightly specified objectives for particular pieces of knowledge or a narrow skill help students to work toward deeper understanding and build expertise, but they have also been associated with and then criticized for narrowing learning—what Harry Torrance (2012) terms “conformative assessment.” However, as Swaffield (2011) pointed out, Elliott Eisner’s (2002) categorization of objectives includes not only these “curriculum objectives” but also “problem solving objectives” and “expressive outcomes.” The latter two are crucial for encouraging exploratory and divergent learning, and for creativity. Students come to understand what they are aiming for and to evaluate their efforts through descriptions of qualities and exemplification, and through process-focused success criteria that separate the objective from the context—a crucial insight from Clarke (2005).

When AfL practice includes the sophisticated use of learning intentions and success criteria, students are not only learning “the curriculum” they are at the same time learning how to learn—in other words, developing and improving lifelong capability for learning. The LHTL project (James et al., 2007) saw AfL as a means of developing learning, with learner autonomy key to both. Thus the learning to which AfL contributes is subject specific, cross-curricular, and generic.

Evidence, dialog, feedback, reflection

Along with the centrality of student agency, and a particular conception of learning, AfL is also characterized by evidence, dialog, feedback and reflection including judgment. Although similar groups of activity are often presented as circular with one leading to another, in AfL their interrelationship is much more complex. For example, evidence may be elicited through dialog as well as being a subject of dialog; reflection on evidence, particularly against learning intentions and criteria, may occur during and following dialog and lead to feedback; dialog may be used to clarify feedback and its implications. The whole process is rooted in cognitive and socio-cultural theories of learning.

Furthermore, it is only when evidence, dialog, feedback and reflection are used and enacted in particular ways that they are characteristic of AfL. Students need to be actively involved, and the focus kept on learning as discussed above. It is the fine details that make all the difference (see particularly Clarke (2014, 2021), Davies (2020), Davies et al. (2012), Marshall and Drummond (2006), and Wiliam (2011b)).

In the moment, simultaneously with teaching and learning

Some aspects of the everyday practice of AfL need to be planned carefully in advance. For example, the teacher being clear about the exact learning intention, the context in which it will be taught (e.g., to know ways of controlling drought, in the context of savannah grassland; listing the different causes of draught, and explaining how these could be reduced (Clarke, 2005)) and pertinent success criteria, and how all this will be shared with and involve the students in the lesson.

Other aspects are contingent and require moment-by-moment decision-making and enactment. Gordon [Stobart \(2014, p. 116\)](#) uses an example of a classroom exchange to illustrate how the right diagnosis and therefore decision depended on the teacher deciding to ask a key additional question and on instantaneous analysis:

Teacher: How much is 7 take away 4?

6 year-old: 2

Teacher: How did you get that answer?

6 year-old: I knew that 7 take away 4 is 2 because I knew 4 plus 2 is 7. And if 4 plus 2 is 7, then 7 take away 2 must be 4.

[Ginsburg \(1997\)](#).

The teacher could have very easily focused on the incorrect answer “2”, or on the different calculation posed at the end of the explanation (“7 take away 2”), but instead recognized the 6 year-old’s sophisticated mathematical understanding as well as weaknesses in basic computation. If the teacher had been relying solely on written work it is highly unlikely that the child’s reasoning would have ever been made explicit. This is why skilled questioning contingent on evidence (of knowledge, understanding and misconceptions) that is often only available in the moment, and dialogic moves that are central to exploring ideas with others (“interthinking” ([Mercer, 2000](#))), play such important roles in AfL.

Principles and strategies

Ten principles

Alongside the 2002 definition, the ARG published ten principles of AfL:

- AfL should be part of effective planning of teaching and learning
- AfL should focus on how students learn
- AfL should be recognized as central to classroom practice
- AfL should be regarded as a key professional skill for teachers
- AfL should be sensitive and constructive because any assessment has an emotional impact
- AfL should take account of the importance of learner motivation
- AfL should promote commitment to learning goals and a shared understanding of the criteria by which they are assessed
- Learners should receive constructive guidance about how to improve
- AfL develops learners’ capacity for self-assessment so they can become reflective and self-managing
- AfL should recognize the full range of achievements for all learners. [ARG \(2002, 2–3\)](#).

As with the definition, the principles were research-based and developed through consultation with a wide variety of individuals and associations. They encompass the key characteristics discussed above, and align with the conception of AfL being explicated in this article. Each principle was accompanied by an explanatory paragraph providing a succinct rationale and a very brief overview of what AfL practice entails, usefully pointing to the complexity of AfL. For example, the fourth principle—AfL as a key professional skill for teachers—is elaborated thus: “Teachers require the professional knowledge and skills to: plan for assessment; observe learning; analyze and interpret evidence of learning; give feedback to learners and support learners in self assessment. Teachers should be supported in developing these skills through initial and continuing professional development” ([ARG, 2002, p. 2](#)). Each element of this elaboration concerns huge bodies of theory, research and practice: for example, one of the very many publications on feedback in educational settings runs to over 600 pages ([Lipnevich and Smith, 2018](#)). This, and the difficulty of remembering ten principles, perhaps places limitations on them as a practical tool for guidance in the immediacy of day-to-day teaching and learning.

Three principles

It is much easier to remember a small number of statements, which is one of the advantages of the three principles that arose from the LHTL project. A survey of staff from 32 schools (junior and senior age ranges) elicited reported practices and values about classroom assessment ([James and Pedder, 2006; James et al., 2007](#)). Factor analysis of data from teachers led to the identification of three groups:

Factor 1: *Making learning explicit*—Eliciting, clarifying and responding to evidence of learning; working with students to develop a positive learning orientation.

Factor 2: *Promoting learning autonomy*—A widening of scope for students to take on greater independence over their learning objectives and the assessment of their own and each other's work.

Factor 3: *Performance orientation*—A concern to help students comply with performance goals prescribed by the curriculum through closed questioning and measured by marks and grades.

James and Pedder (2006, pp. 122–123), James et al. (2007, p. 67).

These three dimensions “provide a sound basis for identifying the fundamental principles that underpin the use of assessment in the classroom” (James and Pedder, 2006, p. 129). “Learner autonomy” is probably a more accurate representation of factor two since it is the students who develop autonomy. Reframing the third factor actively to align with the first two principles, and positively to promote AfL practice, gives a formulation for the third principle of “Focusing on learning” rather than focusing on grades or marks as indicators of performance. The three resulting principles—

Making learning explicit

Promoting learner autonomy

Focusing on learning

(mnemonic LEAF) reflect much other relevant research as the 30 items of the questionnaire were derived from literature—not only about assessment practice per se, but also about underlying principles of learning as well as related processes, contexts and roles (James and Pedder, 2006). The wording of the principles emphasizes that AfL is all about learning—learning portrayed as overt, evidenced, discussed, broader than prescribed curriculum goals or performance measured by marks and grades, and positively engaged with by students who develop greater responsibility for their learning.

The three principles are a framework for thinking about AfL that “holds the promise of providing teachers with a basis for making informed decisions in unpredictable circumstances” (James and Pedder, 2006, p. 129). We have used and promoted these three principles, finding them to be powerful tools for analysis (see the discussion of AfL in East Asian countries below), research, policy, practice and professional development. They provide a common language and coherence for discussions of AfL across varied contexts, as demonstrated by teachers of different subjects working with students aged from 4 to 16 years (Swaffield et al., 2016).

Strategies

The discussion of characteristics of AfL above, and the lists of principles, give a sense of the breadth and complexity of AfL practice. Over the years key strategies central to LfL practice have been depicted in various ways (Black et al., 2003, p. 22; James et al., 2007, pp. 8–12; Wiliam, 2011, p. 46; Davies et al., 2012, p. xi; Clarke, 2014, pp. 6–7). The number of categories vary (between four and 12 in the references just cited), reflecting the breadth, detail and approach to grouping. While authors use different language, and emphasize different aspects, the following list represents commonly accepted strategies of AfL—which importantly are interlinked and not mutually exclusive:

Creating a culture conducive to everyone learning

Clarifying and sharing learning intentions, co-creating success criteria

Developing dialogic talk and worthwhile questioning

Eliciting and evaluating evidence of learning

Engaging in self assessment and peer support

Giving feedback that promotes learning

The first strategy, creating the culture, is to a large extent an outcome of the enactment of other strategies, but listing it separately draws attention to the necessary conscious nurturing of conditions conducive to learning. Every one of the strategies lend themselves to reflecting the three principles of making learning explicit, promoting learner autonomy, and focusing on learning. Moreover, the principles should be used as a check on putative AfL practice and a guide to “authentic” AfL (Swaffield, 2011). This is especially important as the strategies are realized (or not) in multiple contexts through an almost infinite range of techniques whose fine details make all the difference to the quality and quantity of students’ learning. Whichever aspects of AfL are being planned, carried out, or observed, the answers to the questions “Is this making learning explicit? Is it promoting learner autonomy? Is it focusing on learning (rather than marks or grades)?” must be indisputably “Yes, Yes, Yes.” “If practices fail to serve the underlying principles ... then they cease to be assessment for learning” (James et al., 2007, p. 215). The argument that practices are only AfL if they match certain principles underpins differences between AfL and formative assessment.

Distinguishing assessment for learning from formative assessment

The terms “Assessment for Learning” and “Formative Assessment” are often used synonymously, both in published academic work and in practice-orientated documents and discourse. Some consistently refer to formative assessment, others have used both terms over time while a few, not least ourselves, maintain a deliberate and differentiated use. Swaffield (2011) discussed points of difference and argued for explicitly upholding the distinction between AfL and formative assessment.

We have set out our understanding of AfL in sections **Introduction** and **Assessment for learning** above. Crucial determinants are captured by the two linked seminal definitions and the three fundamental principles. The earlier set of ten principles, key characteristics, and strategies also discussed above further elaborate the richness and complexity of AfL. In arguing that there is a distinction between AfL and formative assessment it is necessary to clarify our understanding and use of the term formative assessment.

Formative assessment

According to the Merriam-Webster dictionary, “formative” is an adjective meaning “giving or capable of giving form.” Therefore formative assessment is assessment that forms or shapes something. It often refers to teachers using assessment to inform their teaching, though the formative use of assessment data can also be much broader. Importantly, formative assessment does not—and should not—refer to a particular assessment instrument, but to evidence, interpretation and judgment (as in section **Assessment** above) that is used to make decisions about future action.

For many years following Scriven’s (1967) seminal discussion of formative and summative evaluation, the term “formative assessment” was most commonly found alongside its partner “summative assessment,” referring to two broad purposes of assessment. Formative assessment denotes using evidence and consequent judgments about students’ current learning to inform future teaching and learning. It is contrasted with summative assessment which is concerned with summarizing students’ attainment—often expressed by grades, scores or levels and used particularly for certification, selection, and monitoring. Despite appearing a neat dichotomy and there being very important conceptual differences concerning their prime purposes, they are interrelated in multi-various and sophisticated ways (Harlen and James, 1997), including through the formative use of summative tests (Black et al., 2003).

There are many ways in which assessment data can be used formatively; Wiliam’s (2011a, pp. 10–11, 2011b, pp. 40–43) seven scenarios of the use of evidence of student learning to guide future teaching and learning-related actions illustrate the scope. The first three refer to educators operating at a local or district level, using test scores to make decisions about professional learning, improving teaching, or the provision of remedial classes. The other four feature individual teachers making decisions about their next teaching based on purposefully elicited evidence of their students’ current understanding. The teacher-focused scenarios provide clear evidence of the strategy “engineering effective classroom discussions, activities and tasks that elicit evidence of learning” (Wiliam, 2011a, p. 12, 2011b, p. 46) and of assessment being used formatively. The students demonstrated their knowledge and understanding by handing in quiz papers, completing exit passes, holding up cards to indicate their responses to the teacher’s questions, or showing a sketch on a whiteboard.

Together the scenarios demonstrate that assessment data can be used formatively by a wide range of educational decision-makers not least teachers, to inform the next teaching moment of a lesson, the focus of the next lesson(s), additional instruction during the

year, or teaching in future years. The beneficiaries may be the students who have provided the evidence of learning, or indeed many other students in different contexts.

In summary, formative assessment—the formative use of assessment information—is an educational purpose and a function with a broad scope.

Assessment for learning and formative assessment

Formative assessment and assessment for learning principles

It has been argued above and elsewhere (James et al., 2007; Swaffield, 2011) that practices deemed to be assessment for learning must serve certain principles—specifically making learning explicit, promoting learner autonomy, and focusing on learning.

It is not clear to what extent the examples of using assessment data formatively referred to above involved making learning explicit. There was certainly no mention of clarifying, sharing or understanding learning intentions and success criteria, and indeed doing so would rarely be seen as a natural part of the analysis of either test scores or students' responses to individual questions. The students' role in all cases was to provide evidence of their learning; they were not expected or given the opportunity to take the initiative or to support others. None of the scenarios would have fulfilled the AfL principle of promoting learner autonomy. The teachers' judgments and decisions would undoubtedly have helped the students toward better mastery of the specific learning intentions, but the assessment does not appear to serve the double duty (Boud, 2000) of also helping the students become better learners. The longer time-span examples of using assessment data formatively are particularly problematic for the involvement of students and their development as learners. If information about learning gained from assessment "is used for long-term curriculum improvement, it will not help the learning of the students currently involved. It might be formative for the teacher, but not for the students" (Black et al., 2003, p. 122).

None of these observations should detract from the value of the formative use of assessment data. Teaching, in both the long and short term, should be adapted to students' learning needs—the proactive and retroactive regulation of learning (Allal and Lopez, 2005). They do though illustrate that formative assessment (as understood in section above: **Formative assessment**) does not necessarily involve the students beyond being data generators, nor does it necessarily make them better, self-regulating, learners.

Commentaries, critiques and counter-arguments

Some of the extensive educational assessment literature relates directly to the conceptualizations and interrelationship of AfL and formative assessment. One line of argument concerns their purpose and function, with near universal acceptance that both are intended to inform, and understood to improve, teaching and learning. Function should actually match purpose—assessment information must actually be used. Wiliam (2011a,b), building on his and Black's previous extensive work, stressed the use of evidence for decisions as a defining feature of formative assessment.

The critiques by Harry Torrance (2012) and Shuichi Ninomiya (2016) (who undertook her work during a sabbatical hosted by Torrance) relate particularly to assessment criteria, high-stakes performativity pressures and student autonomy. Their concerns that convergent criteria, conformative assessment procedures and an emphasis on coaching and practice to "close the gap," inhibit the development of independent and critical learners are well founded. However, as has been stated (Swaffield, 2011 and section **Focus on learning** above) explicit criteria do not have to be narrow, and Torrance's and Ninomiya's criticisms do not apply to AfL guided by the three principles. Indeed, their advocacy for developing student understanding and autonomy are served by making explicit the type of learning that is valued, and by promoting learner autonomy; their warning against an emphasis on coaching and practice matches the third principle of focusing on learning rather than performance. The authors conclude that the problems they discuss could be ameliorated by attending to the relationships and interactions between teachers and students—echoing one of Swaffield's (2011) key characteristics of authentic AfL.

Chris Cookson (2018) contrasted three pairs of assessment concepts including formative assessment and assessment for learning. He commented on a number of authors, and found himself broadly in agreement with Swaffield (2011). The reservations he did raise stemmed from his translation into a table of six significant statements about AfL and formative assessment (made by Swaffield after ten pages of explication and discussion). In so doing he interpreted elements within each statement as being mutually exclusive, rather than the more nuanced understanding particularly about emphasis and scope as in the original. Cookson's examination of other authors' difficulties in differentiating assessment and evaluation led him to a preference for the later term. He concluded by proposing replacing the term assessment for learning with "evaluation for learning" as "most suitable as a representative phrase of using testing and the insights derived therefrom, to advance learning and teaching" (p. 939); this despite his apparent acceptance that AfL is much broader than testing. Another critic with testing very much on his mind is Gavin Brown (2019), whose position in his self-declared opinion piece was that AfL cannot be considered as assessment since it cannot meet the technical requirements of tests, particularly in terms of validity, reliability and verification. As argued in 1.1 we (along with many others) do not equate AfL solely or primarily with tests.

Randy Bennett's (2011, p. 6) discussion of "the definitional issue" starts by considering "the distinction between summative and formative roles," before focusing on conceptions of formative assessment as instrumentation (a position often adopted by test publishers) or as a process favoring qualitative insights above scores. His position was that while the prime purpose of formative assessment is to suggest modifications to teaching, it should also be able to give an impression of what students know and can do.

He made a parallel argument for a primary and a secondary purpose of summative assessment—the inverse of those for formative assessment. For Bennett, the terms assessment for/of learning suggested a dichotomous oversimplification, which supported his rejection of the term assessment for learning that he saw as a synonym for formative assessment.

Joanne Baird and colleagues' (Baird et al., 2017) consideration of assessment, learning theories and their relationship included AfL as one of two cases for detailed examination. Their stance was to

... treat Assessment for Learning as offering some distinct emphases within formative assessment approaches. While there is a common function (to directly improve learning), what distinguishes AfL is the focus on student self-regulation and autonomy and on viewing it as an informal and continuous process (p. 336).

These differentiating features resonate with the three AfL principles advocated by James and Pedder (2006) and Swaffield (2011). The focus on learners' self-regulation is also integral to the internationally agreed AfL definition (Klenowski, 2009).

Reasserting the distinctiveness of assessment for learning

The discussion above leads to a reassertion of Swaffield's (2011) argument for the distinctive conceptualization of AfL.

In summary, as agreed by 31 international experts, "assessment for learning is part of everyday practice by students, teachers and peers that seeks, reflects upon and responds to information from dialog, demonstration and observation in ways that enhance ongoing learning" (Klenowski, 2009, p. 264). AfL is underpinned by the three principles of making learning explicit, promoting learner autonomy, and focusing on learning. It is a multi-faceted process, with the purpose and function of supporting learning. Students are the supreme focus; their learning is the primary aim, and their active participation—including the practice and development of the regulation of learning—essential. The beneficiaries of AfL practice are the very students involved, working together in a particular learning context; the decisions are acted on immediately or in the near future. AfL enhances at least two types of learning: it aids students' mastery of the curriculum material being studied; what is more, it helps participants become better learners. AfL is itself a broad educative learning process.

AfL viewed holistically is a manifestation of the formative use of assessment information—that is formative assessment. However, some strategies integral to AfL, for example the sharing of learning intentions, are not in themselves formative assessment. Moreover, many of the ways in which assessment is used to inform future teaching and learning are not AfL (see sections above, particularly **Formative assessment** and **Formative assessment and assessment for learning principles**).

Crucially, AfL (a process) and formative assessment (a purpose and function) are fundamentally and categorically different.

We now extend the discussion of AfL to global contexts culturally different from those where much of the development work and research discussed so far were located.

Assessment for learning and cultural values

Research over the last two decades has revealed issues concerning the implementation of AfL in different countries. Philip Hallinger (2010) attributed cultural factors as reasons behind the obstacles to education reform in Asian countries where the process of implementing "western educational innovations" has been anything but smooth.

While there are cultural differences both among and within countries, the seminal work of Geert Hofstede revealed some broad cultural trends that can influence learner dispositions, namely: (1) virtuous behavior toward others consists of maintaining respect, harmony and not questioning authority, (2) the stability of society is based upon hierarchy and (3) the importance of acquiring skills and education, working hard, being patient and persevering (Hofstede and Bonde, 1988).

A study of the influence of cultural context on the implementation of AfL as an assessment reform in Japan found that while practices such as retaining students' focus on learning and conducting peer lesson observations are common in Japanese school culture, other practices such as those that value students' spontaneity and creativity are sometimes discouraged as language and social customs often emphasize distance (Armito et al., 2015). In Japanese schools, personal effort and silent endeavor are favored over verbosity and group discussions, and there is a long history of undifferentiated group instruction and rote learning. Similarly, researchers considering Vietnam (Ho et al., 2016) opined that emphasis has to be placed on AfL strategies that are situated and culturally relevant, arguing that Vietnamese values such as respect for harmony and hierarchy can either encourage or suppress AfL practices.

Assessment for learning principles and classroom learning culture

In order to explore further the influence of cultural values on AfL practice, we now draw on some regional specific research to discuss the alignment between broadly Confucian cultural trends and the three fundamental principles of AfL (James et al., 2007).

Making learning explicit, behaving virtuously

In the Philippines, students rarely ask questions of their teachers (Cagasan et al., 2020). Power distance is a possible explanation, with students occupying a lower status role than the teacher in the Philippine classroom. The consequence of this is that the student

does not see it as appropriate to question the teacher, which limits the opportunities for the teacher to provide the students with more insight into what is being learned.

The same notion of respect for elders, humility and courtesy, is also entrenched in the Malay culture and in some respect enhances the teaching and learning context within the Malay Language (ML) classroom. According to Roszalina Rawi (2017), the attitudes of ML students in Singapore were different in ML classes compared to other subjects. ML teachers interviewed shared that their students were more positive and respectful in their ML lessons, where even students who had behavioral issues in other classes behaved well. This could be related to the affinity that ML teachers enjoy with their students. Rapport is an important element in the context of classroom learning as it develops a positive learning orientation and makes learning explicit. Learning is facilitated in ML classrooms because of the close bond that stems from the cultural context of ML education itself, and correlates with ML teachers' sense of moral responsibility (Rawi, 2017).

However, for teachers to elicit, clarify and respond to evidence of learning, students need to be vocal and actively question in class. It is unusual for students in an ML classroom to question the authoritative elder figure. Students also feel awkward praising themselves even if they do well, as humility is strongly encouraged in the Malay culture (Rawi, 2017). The sense of moral responsibility that Malay teachers have toward their students encourages them to overcome such cultural norms that inhibit assessment reform. Within the Malay community this sense of moral responsibility is taken seriously. The Malay culture imbues the role of an educator with a larger responsibility than what is normally expected and extends it beyond the formal remit. ML teachers seek to uphold the trust and moral responsibilities expected of them to develop their students' learning potential. Rawi (2017) reported that ML teachers focus on the benefits that their students can derive from AfL, and that the teachers were committed to continued effort to develop their AfL practices because they believed the change would be in the best interest of their students.

Promoting learner autonomy, respecting hierarchy

There are cultural clashes between Western-developed educational reforms that emphasize independent thinking and Asian cultural values that emphasize respect for authority and conformity (Ho et al., 2016). Differences between the AfL principle of promoting learner autonomy and facets of Asian culture are evident. While Vietnamese tradition emphasized harmony and "face saving" (not embarrassing others), these were barriers to developing students' awareness of their current level of learning as they could not be honest and critical. In Vietnam, where respect for harmony and hierarchy are highly valued, the idea of AfL, which changes the power relationship between teachers and learners, may be problematic (Ho et al., 2016). When carrying out self and peer assessment, and reporting to the lecturer in the front of the class, Vietnamese university students training to be teachers seemed to be shy and humble (Tien et al., 2020). They were observed to speak in low-pitched voices, to look obediently toward the lecturer and other students, waiting for their reactions. This is the antithesis of AfL strategies such as active questioning and peer assessment where students need to be vocal, critical and unafraid to challenge the opinions of authoritative figures.

Indeed, within the Asian community the notions of having utmost respect for elders, being humble and soft-spoken are inherent. Western modernity and influences are often regarded with suspicion and thought to encroach on traditional heritage values. When AfL is introduced, heritage language teachers may struggle to understand practices such as allowing students to speak for themselves and to decide their own learning objectives, or to promote peer assessment. These are not processes which teachers and students are used to within the traditional heritage language classroom culture (Rawi, 2017). Hence while AfL may be better received and practiced in other subjects such as English or mathematics, it is crucial to note that cultural processes are deeply embedded in specific learning contexts and a "one size fits all" approach to systemic reform simply cannot work (Chan and Law, 2011; Lynch, 2001).

Resistance to reform due to continued good performance

Despite efforts for reform, the existing norm for assessment practices is very much performance-oriented (Wicking, 2020). In Asian societies standardized assessment concentrates on a competitive examination culture (Leong et al., 2018; Tien et al., 2020). In Singapore for example, pupils are prepared to answer national summative test items correctly through rote learning and repetitive practices. While they are scoring high marks in national examinations, fundamentally they might not have learned much other than how to answer exam questions well (Rawi, 2017). The absence of an AfL culture in schools is an impediment to the development of assessment practices that focus on learning and not performance. AfL was introduced into the Brunei education curriculum alongside school-based assessment (SBAfL) but Bruneian teachers, who were more used to summative assessment procedures, expressed confusion and uncertainties in what SBAfL entails and as a result became less confident in integrating assessment reforms in their lessons (Haji Botty and Shahrill, 2015; Rashid and Jaidin, 2014). Recent formative assessment reform in Japan has emphasized criteria compliance and convergent assessment to reach targets (Ninomiya, 2016). When getting good results is what matters most, and teachers continue with assessment practices which ensure such results, students too become conditioned to expect learning to occur under such circumstances (Sadler, 2007). Research into testing programs shows that the increase in test scores over a period of time is most likely because teachers and pupils have become used to the tests, and not due to increased learning (Harlen and Deakin Crick, 2003).

In Asian classrooms, teachers' beliefs about learning are closely associated with their students' abilities to answer questions and do well in a competitive examination culture (Tien et al., 2020). While teachers consider their close rapport with students, and the freedom to be flexible with the scheme of work as factors that contribute positively to learning, they still hesitate to fully embrace AfL because of exam pressures (Rawi, 2017). Research into the assessment practices in Hong Kong and Taiwanese classrooms showed that there were many gaps between the intentions and outcomes of assessment reforms toward AfL (Berry, 2011; Pan, 2008).

Arimoto and colleagues highlighted a conclusion drawn from the 2014 International Symposium on Classroom Assessment and Afl, which is that “assessment is a matter of culture” (Arimoto et al., 2015, p. 42). Unique Japanese pedagogical techniques such as “neriage” whole-class discussions are deemed as being aligned to Afl as they focus on learning. Although the Japanese ethic of valuing personal effort meant that students seek assistance from their peers less actively than their Western counterparts (Arimoto et al., 2015), moments of peer support still made a positive difference in the learning process for Japanese students. According to a recent study by Wicking (2020) Japanese students in higher learning institutions believed that “peers are able to more or less help each other during assessments” (p. 186) with very little rivalry among them. A majority of these Japanese students engaged in assessment tasks with a sense of camaraderie and mutual support from their peers.

Reconciling Afl principles and East Asian classroom assessment practices

Creating cultures where there are opportunities for teachers to learn in context is a core premise for successful reform. According to Richard Elmore (2004):

The problem [is that] there is almost no opportunity for teachers to engage in continuous and sustained learning about their practice in the settings in which they actually work ... Cultures do not change by mandate; they change by the specific displacement of existing norms, structures, and processes by others; the process of cultural change depends fundamentally on modelling the new values and behaviour that you expect to displace the existing ones (p. 11).

Cultural disconnects between the intentions of those who develop education innovations that have been globally accepted and the perspectives of the local practitioner implementing them have resulted in the stalling of certain reforms (Carnoy and Rhoten, 2002; Pan, 2008). While building rapport with students could indeed be important for meaningful learning, it is necessary for teachers to mediate this aspect of classroom culture with Afl strategies so that students are given the confidence to be autonomous learners. Opportunities need to be made available for teachers to learn how to practice Afl in the context of the East Asian classroom where previously (and perhaps still currently) the existing norm for assessment practices is very much performance-oriented (Rawi, 2017).

Leadership support

The leadership support required for educational reform is associated with the provision of opportunities for teachers to put their learning in context and build their capacity of knowledge (Elmore, 2004; Fullan, 2007). It is necessary for school leaders to create a learning culture for Afl and provide opportunities to engage in learning about Afl within the settings where they actually work. Such a situation helps to develop systematic knowledge about Afl by changing the prevailing culture of assessment within East Asian schools.

Increasing teachers' awareness

Rawi (2017) proposed a new understanding concerning the influence of cultural values in the classroom on Afl implementation. If Afl is to be fully embraced, the challenge lies in reconciling tensions between Afl strategies and learning cultures. In order to enact Afl strategies such as active questioning and peer assessment in classrooms, students need to be vocal, critical and unafraid to challenge the opinions of authoritative figures. These are not character traits inherent in the Asian culture that tends to promote humility, being soft-spoken and respecting elders. As argued by Ho et al. (2016) there are cultural clashes between Western-developed educational reforms that emphasize independent thinking, and Asian cultural values that emphasize respect for authority and conformity.

Teachers need to be aware of such cultural disconnects and mitigate the situation by being consistent and persistent with their Afl practices in order to enculture Afl into their classrooms. Teachers' constant practice of Afl strategies will act as semiotic mediators that produce “qualitative transformations” (Moll, 2014, p. 31) in both the teachers themselves and the milieu in which they are situated (Holland et al., 1998). Indeed, as mentioned by Lynch (2001) a one-size-fits-all approach to systemic reform simply cannot work when cultural processes are so deeply embedded in learning contexts. Chan and Law's (2011) notion of the cultural space within which education reforms evolve is also relevant here. The cultural space of teaching and learning is embedded with traditional values that have to be pragmatically regarded when moderating an initiative such as Afl. Teachers have to make explicit that it is still possible for students to be critical yet respectful when voicing their opinions, and to create opportunities for students to familiarize themselves with such practices by including them in the cultural space of classrooms.

Consistency and persistence are required. As unusual as it might be for Afl strategies such as active questioning and clarifying learning intentions to be implemented in Asian classroom settings, with frequent and systematic practice Afl can be encultured into such classrooms. While East Asian education systems are traditionally seen as intensely competitive, research such as Wicking's (2020) proves that increasing exposure to collaborative learning and group work can result in a change to traditional classroom assessment culture.

Conclusion

Assessment integrated into everyday practice should directly improve learning. Afl (as conceptualized in this article) meets this purpose by developing students as better learners, as well as providing teachers with information to make decisions so that the

content and process of their teaching meets students' learning needs. Learners are active participants in AfL, which is a sophisticated set of practices typified by interrelating strategies that can employ multiple techniques. AfL is best briefly summarized by the definition drawn up by an international group of experts (Klenowski, 2009), along with three principles derived from a multi-university research project (James et al., 2007).

Together the three principles of making learning explicit, promoting learner autonomy and focusing on learning are defining criteria for AfL. As well as being an essential check of whether practices are actually AfL, they can guide planning and implementation. The principles also provide a common language for discussing AfL across contexts (for example subjects, age ranges and countries) where AfL practice may superficially appear quite different. As an analytical tool the principles shed light on the challenges and affordances of implementing AfL in different cultures. Cultural differences exist at scales ranging from the transnational to individual classrooms in one school: particular views and values about the nature of learning and about the teacher-learner relationship can be problematic for AfL practice wherever they occur.

The process of AfL is an example of formative assessment—by which we mean the formative use of assessment. Many valuable ways of using assessment information formatively are not AfL, and some essential elements of AfL are not in themselves formative assessment. The terms are not synonymous.

Many academics and practitioners chose to call what we describe as assessment for learning “formative assessment.” In some respects this does not matter: students' experience and their learning are the most important. But what happens in classrooms is influenced by terminology, and especially by understanding. If educational leaders and teachers (quite understandably) interpret formative assessment as adapting teaching on the basis of student performance, all the agency resides with the teacher, and students will not be developing self-regulating skills and dispositions.

Information technology is an enabler for some ways of using assessment data formatively. Technology-driven learning and testing systems can be designed to incorporate the formative use of assessment information, efficiently and effectively improving students' results on test scores, but the danger is this is at the expense of developing better learners and promoting learner autonomy. Artificial intelligence holds the promise of ever more adaptive learning, but could never replace the knowledge about an individual student that informs a teacher's in-the-moment decisions during a learning dialog. AfL is essentially human, relational and dialogic.

Concerns about the normalization of formative assessment practices that do not adhere to the Klenowski (2009) definition and the three principles (James et al., 2007) of AfL still hold, particularly when it is at the expense of authentic assessment for learning (Swaffield, 2011). Learners and their teachers are the losers, while it may be that test and software developers profit substantially.

Regulation as the function of formative assessment

The function of formative assessment, as practiced in schools and classrooms, is to ensure the regulation of teaching and learning so that students can attain valued learning outcomes. This conception of regulation refers to a dynamic process of adaptation of teachers' and students' actions, rather than to the usage of the term regulation to designate rules that specify prescribed actions (e.g., school system regulations regarding the grading of student work).

Regulation as the function of formative assessment in the classroom has been a key topic in French-language publications since the late 1970s, as described in the reviews in English by Allal and Mottier Lopez (2005) and by Perrenoud (1998). The landmark review by Black and Wiliam (1989) of English-language publications associated with formative assessment highlighted the concept of feedback and its uses, but also referenced research on self-regulated learning which has since gained prominence in the classroom assessment literature.

Formative assessment allows regulation of classroom learning through activities, both formal and informal, that are orchestrated by teachers to assess the learning of students under their pedagogical responsibility and to promote students' involvement in assessment of their own learning. Orchestration of formative assessment by teachers includes the ways teachers use assessment tools provided by the school system, the assessment activities that teachers create and put into practice in their classrooms, and the strategies that teachers adopt to encourage student involvement in assessment. The concept of orchestration highlights the key role of teachers in creating the conditions for formative assessment but also recognizes the role of students as active participants whose actions ultimately determine the effects of formative assessment. Formative assessment, when well designed and implemented, ensures the regulation of teaching and learning through four processes in which teachers and students engage: goal setting, monitoring of progress toward the goal, interpretation of feedback derived from monitoring, adaptation of goal-directed actions and/or adjustment of the goal itself. These processes do not always unfold in a strictly sequential manner. For example, interpretation of feedback may lead to continued monitoring, or to clarification of the goal, rather than to adaptation of instructional activities.

In describing the way formative assessment regulates teaching and learning, Black and Wiliam (2009) proposed a distinction between synchronous contingencies of regulation in which the processes of regulation are closely linked during an activity (e.g., a teacher makes real-time adjustments during a lesson, or a student does so while carrying out a task) and asynchronous contingencies in which the processes are distributed over several points in time (e.g., a teacher uses information from student homework to plan a new lesson, or a student uses feedback from a test to adjust the way of preparing for a subsequent test). Allal (1988, 2020) described three modalities of regulation (interactive, retroactive, proactive) resulting from formative assessment that differ in terms of the temporality of their contingencies. Interactive regulation is based on the student's interactions with teachers, peers, instructional materials, and assessment tools during an on-going learning activity. It entails synchronous contingencies between the processes of goal setting, monitoring, interpretation, and adaptation. Retroactive and proactive regulation involve asynchronous contingencies. In retroactive regulation, formative assessment identifies objectives a student failed to master during a prior phase of instruction and, on this basis, proposes remedial activities so that the student can return to these objectives and overcome difficulties initially encountered. In proactive regulation, information from formative assessment is used to plan new learning activities rather than the correction or improvement of the outcomes of activities already accomplished.

It is generally accepted that formative assessment contributes to the regulation of student learning in an optimal manner when the contingencies are synchronous and interactive: in particular, when formative assessment (1) is integrated within on-going teaching and learning activities; (2) leads to differentiation of activities according to individual students' knowledge, skills, interests, and needs; (3) encourages active student involvement. It is nevertheless recognized that in ordinary classroom conditions, it is

[☆]Change History: May 2021. L. Allal updated the text and the reference list.

difficult to ensure optimal interactive regulation for every student in each learning activity and that asynchronous (retroactive and proactive) modalities of regulation are therefore necessary and useful. This means that the regulation of learning based on formative assessment can include, for example, the following situations: (1) the teacher uses information from an assessment to adapt the remainder of an instructional sequence (adds an extra lesson or a new activity, etc.) for an entire class, but without any individual differentiation; (2) the teacher uses information from an assessment to adapt a lesson plan for future cohorts of students, but this regulation does not benefit the current cohort. Student self-regulation can also include asynchronous actions, for example, a student's decision that it would be useful to return to and review material presented in lessons occurring some time ago, or a decision to not revise an essay, but to take into account peer feedback when drafting a future essay.

Although the regulation of student learning is not the primary function of other forms of educational assessment, all forms of assessment nevertheless influence—and therefore indirectly regulate—the processes of teaching and learning in the classroom. Summative assessment, aimed at the reporting and certification of student achievements with respect to external stakeholders (parents, administrators, potential employers, etc.) influences students' motivation to engage in further learning and their views of themselves as learners. Predictive assessment which determines admission to educational programs or to alternative tracks within a system affects students' access to educational resources and consequently their learning outcomes. Large-scale assessments organized by the education system provide data that guide policy, school curriculum and teacher education, all of which indirectly impact student learning. In short, all forms of educational assessment participate to some degree in the regulation of learning. While the implementation of formative assessment is influenced by the actions and decisions of policymakers, teacher educators and school leaders, teachers nevertheless remain the key initiators of formative assessment practices that regulate teaching and student learning in the classroom. In addition, because teachers are responsible for carrying out summative assessments prescribed by the school system, they are constantly faced with the challenge of coordinating formative and summative assessment.

This article examines in more detail four aspects of the relations between formative assessment and the regulation of student learning:

- the implications of different theories of learning for the conception of formative assessment,
- approaches to formative assessment that emphasize external regulation resulting from teacher actions and the structure of learning environments,
- practices of formative assessment emphasizing students' active engagement in processes of self-regulation,
- conceptions of formative assessment as a process of co-regulation resulting from the joint influence of contextual factors and student self-regulation.

The final section of the article discusses the question of continuity between formative and summative assessment in the classroom and the consequences for the regulation of student learning.

Implications of theories of learning for formative assessment

All theories of learning propose a mechanism of regulation that ensures adaptation of the learner's behavior and thought processes. Well-known mechanisms include reinforcement in behaviorist theory, equilibration in Piaget's constructivism, feedback devices in cognitive models, and social mediation in sociocultural and social constructivist approaches. Although there are important differences among these theories, they all consider processes of regulation to be a central feature of learning.

Formative assessment in the classroom was first proposed by Bloom (1968) as a key component of his model of mastery learning formulated in a neo-behaviorist perspective emphasizing external sources of regulation—namely, formative tests, corrective feedback, and remedial resources provided to students by the teacher. As other theories of learning came into prominence, they led to re-conceptualizations of formative assessment. Drawing on constructivist and cognitive theories of learning, Allal (1979) proposed that formative assessment be based on well-designed tasks that reveal salient aspects of students' reasoning and conceptual understanding, coupled with classroom observations and interactions (teacher-student interactions, peer interactions) that allow monitoring of learners' progression, as well as interactive regulation integrated in teaching/learning activities.

Two theoretical developments helped to further define processes of regulation to be taken into account in formative assessment. One was the work on metacognitive regulation of learning, notably by Brown (1987) who analyzed the processes of self-regulation in a Piagetian perspective and of "other-regulation" in a Vygotskian perspective. The second was the elaboration of the social cognitive theory of learning by Bandura (1986) who emphasized the role self-efficacy beliefs in the regulation of the learner's task engagement and motivation. Bandura's theory had an important influence on the models of self-regulated learning which have become increasingly prominent in the formative assessment literature (see the chronological review by Panadero et al. (2018a)).

A seminal paper by Shepard (2000) traced the long-standing influence of behaviorist and neo-behaviorist learning theories on educational assessment and the emergence of a transformed paradigm of classroom assessment based on cognitive and constructivist learning theories, as well as on Vygotskian concepts of social mediation and scaffolding. Other researchers developed in more detail the implications of sociocultural theories of learning and of theories of situated cognition for classroom assessment (Allal and Pelgrims, 2000; Dann, 2014; Gipps, 1999; Hickey, 2015; James, 2008). One important contribution of this work is the recognition of the interdependence between other-regulation (by a teacher, a mentor, a peer) and the self-regulation of the learner. This means that scaffolding should not be seen as something done *to* students but as something done *with* students. Another major

contribution, particularly from the situated cognition perspective, is the idea that formative assessment concerns not only the regulation of learning but also the formation of students' identity as learners and as participants in a learning community.

In a special journal issue on the relations between learning and assessment, the lead article by Baird et al. (2017) discussed why learning and assessment sometimes appear to be "fields apart" and why new forms of synergy are needed for classroom assessment and for large-scale assessment. Multiple commentaries on this article provided a range of perspectives on learning and assessment.

Formative assessment and external regulation of learning

The distinction between formative and summative evaluation was proposed by Scriven (1967) in an article on the methodology of curriculum and program evaluation conducted by researchers and school administrators. In the mastery learning model developed by Bloom (1968) and Bloom et al. (1971), this distinction was transposed to the assessment of student learning by classroom teachers. Mastery learning was formulated in a neo-behaviorist perspective emphasizing external sources of regulation that guide and reinforce student learning, namely:

- the communication of instructional objectives, defined by curriculum specialists and teachers, at the beginning of each instructional unit;
- the use of formative tests at the end of each instructional unit to identify the objectives attained and those not attained by each student;
- for the objectives not attained, the organization of remedial activities for the students in question: allocation of additional time and assignment of appropriate correctives (prescriptive feedback) and alternative resources designed to promote mastery.

Criterion-referenced summative tests, covering the objectives of several units, are subsequently administered to determine students' final level of achievement in a domain.

In this approach, the teacher is responsible for finding effective means of instruction and assessment to ensure the regulation of student learning. The student's role is to execute diligently the tasks (formative tests, remedial activities) prescribed by the teacher. The mastery learning model recognizes that internal processes (students' prior knowledge and motivation) are important, but its focus is on retroactive regulation from sources in the learning environment.

Although the mastery learning model has been criticized by proponents of other theories of learning, it is important to recognize two major contributions of this model. The first is its radical break with the traditional notion that success and failure in school learning are determined by purely internal dispositions of the learner (aptitude, ability, intrinsic motivation). A second contribution is the idea that formative assessment provides a profile of information for each student (indication of objectives attained and not attained) and that the resulting adaptation of instruction is differentiated according to the profile of student outcomes. The linkage between formative assessment and the differentiation of instruction remains an enduring heritage of the mastery learning model.

External forms of regulation can of course be implemented by other means than by a teacher, for example, by embedding formative assessment tasks in curriculum materials. The development of computer-based learning and assessment environments has led to more powerful ways of providing sources of external regulation to be used by teachers and by students (Bennett, 2015; Tomasik et al., 2018). These environments enlarge the scope of mastery learning by the inclusion of features (e.g., generation of items as a function of the student's responses and errors) that allow synchronous interactive regulation, as well as periodic retroactive regulation. Another feature of these environments is the possibility of data aggregation to ensure a formative assessment continuum from adaptations of teaching and learning in the classroom to system-wide adaptations of curriculum and policy. In upper secondary and higher education, computer-based tools sometimes function in a stand-alone way without any teacher intervention, but in classroom settings with younger students, the teacher usually has an important role in the orchestration of how these tools of formative assessment are deployed and used by students.

Formative assessment and self-regulation of learning

In constructivist, cognitive and social cognitive theories of learning, external sources of regulation can enhance or inhibit processes of self-regulation, but learning occurs only when self-regulatory mechanisms intervene in the transformation of existing knowledge and skills. Student self-regulation, which had been discussed episodically in the formative assessment literature, became the primary focus of the chapter by Andrade (2010) entitled "Students as the definitive source of formative assessment." She defined the relation between self-regulation and formative assessment by associating the three recursive phases of the Zimmerman (2000) model of self-regulated learning with the questions from the Hattie and Timperley (2007) review of feedback and its effectiveness. This led to a definition of student self-regulation in formative assessment as follows:

- Forethought: "Where am I going?"
- Performance and control: "How am I doing?"
- Reflection: "What's next?"

Classroom practices of formative assessment, she argued, should create the conditions which allow students to actively engage in these self-regulatory processes.

Research on self-regulated learning has been a very productive field of investigation leading to multiple models (reviewed by Panadero, 2017) with key insights for the conceptualization of formative assessment. In addition to the models describing recursive phases of self-regulation, the dual process model of Boekaerts (2011) is of particular interest because it postulates two simultaneous directions of self-regulation: a growth pathway linked to (meta)cognitive regulation and a well-being pathway linked to motivational regulation. In some cases, formative assessment practices aimed at providing positive support for (meta)cognitive regulation of learning can have detrimental effects on motivation. For example, detailed feedback on improvements and revisions that a student is expected to carry out can sometimes trigger a self-protective coping strategy leading to inaction. The opposite could also occur: a formative assessment practice could foster student motivation (e.g., an attractive activity with little domain-content structure) but not ensure progress in the acquisition of more advanced skills and cognitive competence.

Student involvement in formative assessment can be enhanced in several ways in the classroom: by whole-class discussions between teachers and students about learning goals and assessment criteria, by students' active engagement in self-assessment procedures, and by students' participation in various forms of peer assessment. A review of research on student self-assessment by Andrade (2019) emphasized the importance of finding ways to integrate cognitive and affective mechanisms of self-assessment and self-regulation. Referring to research on self-assessment and on peer assessment, Panadero et al. (2016) proposed a series of guidelines for teachers who wish to create conditions that encourage active student involvement in formative assessment. A "roadmap" for fusing self-regulated learning and formative assessment was subsequently formulated by Panadero et al. (2018a) based on their review of 33 publications that provide insights and empirical data concerning relations between self-regulation and formative assessment. In the introduction to a special journal issue, Brandmo et al. (2020) discussed the convergent aims of formative assessment and self-regulated learning, as well as factors that may limit implementation of high-quality practices in the classroom.

A major contribution of the above publications is their specification of the processes of self-regulation in which students need to engage for learning to effectively take place and the assessment practices that are likely to foster these processes. For example, goal setting initiated by the teacher, using curriculum materials that define assessment standards, can through whole-class discussions and analysis of exemplars enhance student understanding of standards and also incorporate students' suggestions about how standards can be exemplified in a formative assessment tool. Although approaches emphasizing student self-regulation recognize and promote sources of external regulation that can support and enhance self-regulation, they consider external regulation as a means that will ultimately allow students to become autonomous self-regulated learners.

Formative assessment and co-regulation of learning

There are several different conceptions of co-regulation and its relationship to formative assessment (Allal, 2020). Hadwin and Oshige (2011) proposed an enlargement of the field of self-regulated learning to include three categories: self-regulation, which entails active monitoring and regulating of one's own learning; co-regulation, which is considered as a transitional process in the learner's appropriation of self-regulation strategies through interaction with a more capable other (teacher, more advanced peer); socially shared regulation, which refers to co-constructed regulation by multiple participants (of equivalent status) who ensure the progression of their shared activity. For other researchers (Volet et al., 2009), co-regulation refers to any socially mediated regulation, whether with a more capable other (teacher or more advanced peer) or with peers of equivalent status. With a focus more specifically on classroom assessment, Andrade and Brookhart (2020, p. 350) defined co-regulation as "regulation by others" resulting from teachers' interventions, from other students, from instructional materials, and from assessment practices. They enumerated for each phase of the Pintrich and Zusho (2002) model of self-regulated learning (forethought, monitoring, control, reaction and reflection) the attributes of self-regulation and the corresponding attributes of co-regulation in four areas: cognition, motivation, behavior, context. Their discussion provided many indicators for developing the regulation of student learning through classroom assessment, but largely retained the self-regulated learning premise that co-regulation is a means for helping students become autonomous self-regulated learners.

A model of co-regulation based on the perspective of situated cognition and learning has led to a different conception of its relationship to formative assessment (Allal, 2007, 2020). In this model, co-regulation is defined as the *joint* influence on student learning of the learner's processes of self-regulation and of the sources of regulation in the learning environment: namely, the structure of the teaching/learning situation; the teacher's interventions and interactions with students; the interactions between students; the tools (materials, artifacts, instruments) used for instruction and for assessment. In this perspective, co-regulation is not one type of regulation among others but an overarching construct that bridges the internal-external regulation distinction. Moreover, co-regulation is not a transitory process or a support system to allow students to become autonomous self-regulated learners. Rather it is a general function of instruction and assessment in classroom communities where students learn to participate in increasingly complex and diversified forms of co-regulation.

In this model of co-regulation, students' interactions with teachers and peers are the dynamic force moving learning forward but tools, and in particular assessment tools, have several important functions. (1) Tools ensure linkages between the different sources of external regulation (situation, teacher, peer) and the learner's self-regulation. For example, the teacher may select an assessment rubric provided by the curriculum materials and then conduct a whole-class discussion during which more specific success criteria are defined and illustrated; the resulting extended rubric may then be used by students both for peer assessment and for self-assessment. (2) Tools can amplify the effects of interactive co-regulation by making the goals more explicit and the monitoring

of progress more systematic than would be the case in informal interactions without assessment tools. (3) Tools often allow recording of traces of assessment that can be used for deferred regulation. For example, when a group of students assesses its collaborative writing activity using a checklist, this information can be subsequently used by the teacher to prepare a new classroom activity designed to help students overcome previous difficulties.

An article by [Panadera et al. \(2018b\)](#) proposed an extension of the Allal definition of co-regulation to encompass not only the effects on the student (assesse) but also the effects on the teacher or peer assessor. An interesting topic for future research would be to document how assessors, particularly teachers, learn to improve their interventions through their participation in formative assessment interactions with students.

Continuity between formative and summative assessment

Formative assessment coexists in the classroom with the summative assessment procedures that are prescribed by the school system. The development of continuity and coherence between these two functions of assessment is in the interest of both teachers and their students. A starting point is the alignment of formative and summative assessment activities and tools with well-defined curriculum goals and descriptions of learning progressions. In addition, it is important that teachers develop a classroom assessment culture that allows students to understand the linkages between different assessment activities and the primary purpose, or in some cases multiple purposes, of each activity.

The information from summative assessments (e.g., grades in report cards) influences student motivation and engagement in learning ([Brookhart, 2001](#)): the effect is often positive for high-achieving students but can be detrimental for other students. Despite the differences in the basic purposes of formative and summative assessment, and the negative effects of some forms of summative assessment, the question can be raised as to their possible synergy in promoting student learning ([Harlen, 2005](#)). Can summative assessment actively support student learning? Can it contribute to what the UK Assessment Reform Group ([ARG, 1999](#)) termed “assessment for learning”?

It has been argued by [Black and Wiliam \(2009\)](#) that any given assessment activity or instrument, depending on how the resulting information is used, could have a formative and/or summative function. [Bennett \(2011\)](#) has similarly claimed that well-designed assessment instruments or systems can serve both functions, albeit with primacy often given to one function or the other. These views provide openings for continuity and possible synergy between formative and summative assessment. [Laveault and Allal \(2016\)](#) have proposed that the ARG concept of assessment for learning, which is often treated simply as a synonym for formative assessment, can in fact encompass both formative assessment practices and practices situated in an interface between formative and summative assessment. This interface includes:

- use of information from summative assessments to implement the regulation of teaching and learning activities (e.g., results from an end-of-term test included in students’ report cards are also used to organize remedial activities for some students);
- use of information from formative assessments to enrich summative assessment reports (e.g., observations from formative assessment activities are integrated in comments about students’ grades in their report cards in order to provide a more complete picture of student competencies);
- assessment activities that include phases or components with a formative function and other phases or components with a summative function (e.g., in portfolio-based or project-based assessment, teachers provide feedback and advice about student plans and progress, but subsequently formulate a summative appraisal of the final product).

Although assessment activities with a strictly formative function are generally the most powerful means for ensuring the regulation of teaching and learning, it is important to recognize the role of activities in the formative-summative interface which, if well-conceived and conducted, may also contribute to the progression of student learning.

There remain, nevertheless, many forms of summative assessment used for reporting that are inappropriate for the regulation of student learning in a productive way. Examples would include norm-referenced summative assessments, assessments that summarize achievement by a single outcome measure rather than a profile of outcomes, and summative assessments that are so frequent and time consuming that there is little space for the adaptation of teaching and learning.

To conclude, many challenges still exist, of which two will be mentioned. The first is the adoption by school systems of summative assessment practices that—at the least—are not detrimental to student learning and—at best—provide positive support for the regulation of teaching and learning. The second is the promotion of school-based teacher professional development in the area of classroom assessment so that teachers can share their assessment practices and ways of coordinating formative and summative assessment, and thereby develop a collaborative assessment culture across classrooms.

Feedback can powerfully influence learning. Meta-analyses consistently show that feedback has a statistically significant effect on performance, recently revised from a high (0.7) to medium effect (0.48) (Wisniewski et al., 2020). However, across these reviews and others (Evans, 2013), there is significant heterogeneity in the data indicating diversity in feedback practices and effects with almost a third of interventions reportedly having negative effects on learners (Kluger and DeNisi, 1996). Here we grapple with this diversity of feedback interventions through highlighting differences in conceptualization of feedback and how it has influenced practice and research. We then discuss four contemporary trends in feedback research which show promise for improved cognitive (e.g. achievement of learning outcomes, development of evaluative judgment) and affective (e.g. motivation) effects on learners. Finally, we present several emerging ideas from feedback research.

Conceptualizations of feedback

First, we map significant differences, or shifts, in conceptualizations of feedback in research and how these have influenced practice. This is by no means the only way to categorize the field, nor is it meant to be systematic or exhaustive. Instead, this synthesis of significant shifts in conceptualization is a result of years of scholarship in the field and our interpretations and frames of reference. Further, research continues strongly in each of these categories to this day, so while some researchers have “shifted” others maintain important scholarship within these domains.

Information transmission

The “traditional” approach to feedback is one of information transmission. Here feedback is conceptualized as information provided by an agent regarding aspects of one’s performance (Hattie and Timperley, 2007). Research in this tradition focuses on what the teacher does and the form and content of the message (i.e. the feedback). Feedback is thus an “input”. The source of this input may be a significant other, peer, book, self, or teacher, with the majority of research focusing on teacher delivery of feedback information often in written form and often in response to submitted work. Context is presumed mostly irrelevant and therefore advice stemming from such a perspective focus on the message and might include a focus on specificity, timeliness, balanced comments, etc. These criteria serve to help us judge the quality of feedback.

Recent work in this tradition of feedback as information does acknowledge the role of the learner such as Lipnevich and Smith (2018), who defined feedback as any information about a performance that learners can use to improve their performance or learning. However, that feedback actually improves performance is either assumed or hoped for (Boud and Molloy, 2013). Feedback may be *given* at the level of the task, process of how to do a task, regulatory or metacognitive process level, and/or the self or personal level (Hattie and Timperley, 2007). The language of this tradition involves delivery, giving, and metaphors such as feedback as a gift, are common. Students report feedback as something done to them rather than with them; and they are passive recipients if they are acknowledged at all (Boud and Molloy, 2013).

Critique of this conception of feedback abounds, briefly, it includes that information (generally) ignores the role of the learner in the feedback, and there is no certainty about whether following the provision of information it has been read, understood or if the

learner can or is willing to act on it. There is also a lack of attention to further specific opportunities where the student may apply this information. Jonsson (2013) identified five reasons for students not to engage with feedback as information: (1) students do not find it to be useful, (2) it does not meet their needs, (3) they find it difficult to decipher, (4) it serves to justify the grade rather than promote learning, and (5) the lack of strategies for improvement. Proponents of feedback as information might argue that with the “right” information these problems may be addressed. However, those who advocate for more constructivist perspectives on feedback would argue that the focus on information and its delivery is too narrow to achieve the purpose of feedback for learning. Rather than focusing on what the teacher does, there is a need to focus on what the learner does.

Constructivist

The absence of the student in the previous discourse, led some scholars to argue for a more constructivist approach that foregrounds the learner. Definitions of feedback thus shift from an input to a “process” whereby learners obtain information about their work in order to appreciate the similarities and differences between the appropriate standards for any given work, and the qualities of the work itself, in order to generate improved work (Boud and Molloy, 2013). Alternatively, feedback has been defined as “dialogic processes whereby learners make sense of information from various sources and use it to enhance their work or learning strategies” (Carless, 2016). Language in this discourse talks of students engaging with feedback processes or being active recipients of feedback information (Winstone et al., 2017). The teacher’s role includes delivery of information and creating the conditions for students to interpret and use feedback information through deliberate feedback designs. Feedback is thus a *process* of meaning making and action by the learner. The analytical research lens is therefore trained to foreground the learner and examine their responses as they interpret the information in context.

Given the learner’s active and interpretive stance, emotions become more relevant and influence how feedback is interpreted and acted on. Although significant swathes of literature, align negative feedback comments with negative emotions and lack of action (deactivating) and positive feedback with positive emotions and action (activating), some show more nuance. For example, Goetz et al. (2020) work on emotions, drawing from Pekrun (2006), show that positive emotions (e.g. relief) may be deactivating and negative emotions (e.g. anxiety) may be activating. There are also more complicated individual and context interactions, for example a high achieving student who reaches their goal of a pass may choose not to make further revisions despite positive comments (Ajjawi et al., 2022a) or a student who engages with negative comments because they recognize and trust the teacher’s intentions (Telio et al., 2016). Students’ perceptions of feedback and its effects are thus context-dependent, subject-dependent, and individual-dependent (Van Der Kleij and Adie, 2020).

Students are provided greater agency, and pedagogical design as a mechanism for prompting student sense making and use of feedback is also in greater focus. The extreme of this shift might argue that feedback is only so if it makes a difference in student thinking, action or work. In other words, feedback should be judged by its effects on learners (Henderson et al., 2019). Feedback designs touted here include nested tasks, sequenced tasks, formative tasks and dialogue. Feedback “no longer needs to be something that comes just at the end of an assignment but needs to be put into a context and integrated into students’ overall learning” (Orsmond et al., 2005). The recognition of the potential value of peers within feedback processes has also been recognized (Nicol et al., 2014). However, the extent to which the student plays an active role in the feedback process varies even within conceptualizations of feedback that consider the critical role of the student (Van der Kleij et al., 2019).

Critique of the constructivist conceptualization is that feedback should not be judged by its effect as this introduces many variables including student capability, agency, volition, and interest, alongside the design of opportunities to demonstrate an effect. Further, constructivist conceptualizations of feedback that foreground learners’ interpretation blurs the divide between teaching and assessment (Pokorny and Pickford, 2010). From a practical perspective, greater effort and time is needed in designing assessment to promote feedback loops. In addition, students do not have free will to act as they choose, instead their agency is bounded and mediated by social, relational, political and cultural factors and these factors strongly influence feedback practices.

Sociocultural

The third shift is one of feedback as a process of co-construction. Co-construction rests on principles of shared understanding and working (Reusser and Pauli, 2015). Here too feedback is a “process”, but one that is entwined within the cultures which produce it. Core to this conceptualization is the notion of “feedback practices”, that is, the processes, relations and interactions that take place when students and teachers are engaged in feedback interactions (Esterhazy, 2019). Here context is not merely a neutral container that individuals make sense of and control, instead learning cultures/environments fundamentally imbue and shape feedback practices and the ways in which teachers, learners, peers and others respond can be productive or detrimental to learning. Issues of power, relationality, socio-historical factors are enmeshed with what individuals bring, from which feedback unfolds.

Sociocultural theories of feedback conceptualize it as meaning-making trajectory students move along by orienting toward and elaborating on both task-specific and general-knowledge content (Esterhazy and Damşa, 2019). Meaning-making processes are supported by tools and capacities that are available to the students. One way to think of this is that if learning environments are rich with performance relevant information and scaffolding, learning necessarily ensues. Another definition elaborates feedback as “a dynamic and co-constructive interaction in the context of a safe and mutually respectful relationship for the purpose of challenging a learner’s (and educator’s) ways of thinking, acting or being to support growth” (Ajjawi and Regehr, 2019). The relational

dimension of feedback is also accounted for, a recognition that there should be trust, and that this is dynamic and fragile but it influences how teachers and learners interact and enact feedback practices. Emotions are not merely reactions to feedback but influencing of feedback behaviours and indicative of the learning environment (Ajjawi et al., 2022b).

The unit of analysis in this discourse can be the feedback culture, or teacher-student-peer groups, none are prioritized but could be foregrounded at different times with the understanding that they influence each other. Culture can refer to “behaviors, values, norms, beliefs, assumptions and attitudes that are found within a particular organization or context” (Bearman et al., 2021). Research shows that feedback cultures differ between for example school and higher education (Tian and Lowe, 2013), university and workplace settings (Urquhart et al., 2018), and between different professions/disciplines (Watling et al., 2013) or ethnic groups (Tian and Lowe, 2013). Feedback practices common to a particular culture might feel foreign, personal and devastating in another.

Critique of sociocultural approaches to feedback include that, “culture” is an amorphous term, despite regular appeals to culture change, it does need to be approached from a specific theoretical perspective such as through organizational or practice theories (Watling et al., 2020). In addition, defining feedback so narrowly excludes from analysis much of what may be understood elsewhere as feedback. Privileging human relationships places less emphasis on the feedback information learners receive from material sources, both traditional formal feedback (e.g. MCQ feedback) and cues from the environment.

Trends in feedback research

We now synthesize four contemporary trends in feedback that research suggests might improve the effectiveness of feedback interventions on student learning. These four categories cross-cut the above conceptualizations but do undeniably privilege the learner and the learning environment.

Deliberate and iterative feedback designs

The landmark paper that highlighted the importance of feedback design was by Boud and Molloy (2013). They described the need to create opportunities for learners to apply feedback information and to show that performance had indeed changed. The recognition of a need to be able to detect a change in performance was also evident in earlier definitions of feedback: “information about the gap between the actual level and the reference level of a system parameter which is used to alter the gap in some way” (Ramaprasad, 1983).

Findings from a recent realist review suggest that feedback often has a limited impact because of the lack of action and practice that accompanies it, hence the need for cognitive scaffolding through task design (Ajjawi et al., 2022a). An important feature of deliberate feedback design is iteration, that there are multiple/repeat practice opportunities, not just one-off demonstrations of effects (a deliberate closing of the feedback loop). Three design features of impactful learner-centered feedback are: that feedback processes are designed to promote learning, comments invite feedback dialogue, and comments provide actionable information for future performance (Ryan et al., 2020). Designs that promote learning include formative assessment opportunities which can lead to improved performance for those students who are organized and motivated enough to submit (approximately 20–50% of students). This prompted Beaumont et al. (2016) to make the formative task compulsory. A suitable compromise appears to be to make the activities count (i.e., not optional) through sequenced task design. This equalizes opportunities for feedback across students of varying levels of competence.

Students were more likely to use feedback information when tasks were sequenced (Steen-Utheim and Hopfenbeck, 2019). Other examples of tasks that prompt students to become more active in the feedback process include: the use of proformas such as interactive cover pages (Bloxham and Campbell, 2010; Daniel et al., 2015), reflective tasks to process information (Hughes et al., 2015; Todd and McIlroy, 2014), action planning (Adcroft and Willis, 2013), and feedback dialogue (Ajjawi and Boud, 2018). Gamlem and Vattøy (2023) also highlight the importance of dialogue between a student’s internal feedback and feedback provided by external agents. Feedback loops and relevant education about feedback has also been shown to be useful in relation to peer feedback (Mercader et al., 2020). Recent research shows improvements in student engagement with feedback as a result of ipsative design processes (Malecka et al., 2021).

Students are reported to use feedback to identify the teachers’ expectations rather than for learning (Orsmond and Merry, 2011). The best designs can be undermined if students simply believe they are going through a process to satisfy a teacher. They can also find it difficult to transfer learning from feedback comments to other tasks with similar learning outcomes. Iterative feedback designs signal to students that the purpose of feedback is to support learning rather than merely justifying the grade. Hence, scaffolded feedback designs can help students and teachers to reach a common understanding as to the purpose of feedback. Overall, the evidence suggests that there are benefits to trying to make students more active in the feedback process but an awareness of the extent of engagement with feedback across the continuum of ability must be considered in design decisions (Ajjawi et al., 2022a).

Feedback literacy

There has been a growing realization that individuals require capabilities for effective feedback, regardless of which feedback paradigm is adopted, termed feedback literacies. The requisite capabilities were initially introduced by Sutton (2012) who applied an academic literacies approach, which argues for literacy as a social practice undertaken within contexts—more than just to read and

write. The focus of this work was on the promise of feedback literacy to contribute to overall student development in higher education, in how they know, who they are becoming, and how they might act as a result of feedback. Carless and Boud (2018) reframed the concept of feedback literacy as “an understanding of what feedback is and how it can be managed effectively; capacities and dispositions to make productive use of feedback; and appreciation of the roles of teachers and themselves in these processes”. They identified four inter-related features which students needed to do for effective uptake of feedback: appreciating feedback, making judgments, managing affect, and taking action. This framework was expanded upon by Molloy et al. (2020) in an empirical study, to denote more fine-grained behaviors and actions that feedback literate students might exhibit. These behaviors include attitudinal aspects, “commits to feedback as improvement”, “appreciates feedback as an active process”, and “acknowledges feedback as a reciprocal process” in addition to categories that aligned with the previously identified features of student feedback literacy. This framework identified that being a producer of feedback information for others—such as peers—is a key part of feedback literacy.

Researchers have subsequently applied different perspectives to the concept of feedback literacy, to develop an ecological model where the role of environment and context are acknowledged (Chong, 2021), to draw out sociomaterial implications which place further emphasis on the entangled nature of students and teachers with their context-bound environments (Gravett, 2020; Tai et al., 2021), and understand how feedback literacies vary in different disciplinary contexts (Winstone et al., 2020). This work suggests that both students and teachers must be able to detect, understand, and adapt to the various feedback situations they find themselves in, rather than having just one set of feedback capabilities to apply consistently across those different situations. One aspect of feedback literacy has been likened to a related concept in the organizational studies literature, feedback-seeking behavior (Joughin et al., 2021) which, as the nomenclature implies, focuses on the individual within workplace contexts, and what attitudes and dispositions are required to successfully elicit information about their performance. While student feedback literacy was the initial focus of work within education (e.g. Sutton, 2012; Carless and Boud, 2018; Molloy et al., 2020), teachers’ feedback literacy is also increasingly researched, both in their roles as academics (Gravett et al., 2020), and in how they interact with their students (Chan and Luo, 2021; van Heerden, 2020; Xu and Carless, 2017; Carless and Winstone, 2020). Teacher feedback literacy matters as they have considerable influence in designing feedback processes and in setting expectations of students about feedback (Boud and Dawson, 2021).

Across all the work that has been conducted so far on feedback literacy, the key implication is that successful feedback—whether it be the creation of performance-relevant information, or the participation in co-construction of understanding in relation to performance and standards—requires the development of capabilities, and this in turn requires appropriate opportunities for learning. We cannot expect students or teachers in any situation to instantly participate well in feedback for learning without a clear conception of what feedback is for, orientation and practice. Therefore, attention must be paid to the sequencing of learning opportunities about feedback, in addition to crafting the feedback opportunities themselves.

Technology and feedback

There is an expansive research literature on technology and feedback (Dawson et al., 2018), which can be characterized in different ways. One is to focus on the particular types of technology in use. In a recent systematic review, Dawson et al. (2018) identified the main types of feedback technologies as: digital recordings, “bug in ear” technologies (e.g. a Bluetooth headset) that allow real-time feedback dialogues with someone who is not physically located with the learner, automated feedback, and “intelligent tutoring systems” which build a cognitive model of the student and provide feedback information in response to student performance. They found evidence of efficacy for all of these approaches, though caution that ultimately it is the underlying feedback design that will likely have the most impact. Another approach is to consider who is generating the feedback; in that same systematic review the main generators of feedback information were students, their peers, their teachers, and computers. In this section we take a different approach, by considering the main affordances of feedback technology: richer feedback communication through digital media; logistical enablement of more sophisticated feedback designs; and the generation of additional feedback information.

Media switches (such as written to audio or video feedback) are one of the most researched areas at the intersection of technology and feedback. In these approaches, rather than delivering feedback information to students through written comments, alternative media are used. Three media switches that are heavily researched are when educators shift to (1) audio, (2) video or (3) screen cast. Reviews of these different modes concur that students tend to like feedback more when it is delivered by these digital media (Killingback et al., 2019; Mahoney et al., 2018; Bahula and Kay, 2021). In addition, there is evidence of affective and/or relational benefits, as these modes allow richer verbal and non-verbal communication like gesture and tone of voice. Other benefits include greater efficiency for some educators (Henderson and Phillips, 2015), though this comes only once some technical hurdles have been overcome, and greater perceived detail and usefulness of the feedback for students (Ryan et al., 2019).

There is one gap in the feedback media switch literature: robust, replicated evidence that media switches are associated with improvements to learning. This may be partially because many studies have largely focused on student perceptions and experiences (Mahoney et al., 2018; Killingback et al., 2019). More generally in education, when educational designs are held constant but the mode of instruction is changed, educational outcomes tend not to get better (Clark et al., 2005); this has been dubbed the “No Significant Difference Phenomenon” (Russell, 2013). If this effect applies to feedback as well, it suggests that simply implementing the same feedback design through a different mode may not yield significant improvements to learning. However, changes in mode may prompt changes in design, which might lead to improvements to learning.

Technology can also be used to support the logistics of feedback designs that would otherwise be infeasible. For example, bug in ear technologies allow access to outside expertise, and online peer review platforms support the scalability of peer feedback

approaches to thousands of students (Dawson et al., 2018). This logistical enablement also extends to supporting online equivalents of face-to-face learning activities that incorporate feedback, such as discussion (e.g. discussion boards) and collaboration (e.g. wikis). As with feedback media switches, the effectiveness of these approaches in supporting improvements to student learning is under-explored in the literature (Dawson et al., 2018). But as these approaches support the implementation of feedback designs that may usually be infeasible in mass higher education—for example, the 360° feedback approaches used in business contexts (Corrin and Bakharia, 2020)—they are not just doing the same thing, but online. However, as they are new designs requiring more from learners, they also bring challenges that are not just technical. For example, sophisticated online peer feedback designs require a range of non-technical capabilities and attitudes of learners and educators, in addition to capability with technology (Tai and Adachi, 2020).

In addition to being a medium or enabler of feedback, technology can also itself be a provider of feedback information for students. Dawson et al. (2018) identify five types of computer-to-student feedback. At the most rudimentary level, computers can provide pre-programmed feedback information on multiple choice questions, which provides significant support in terms of correcting student misunderstandings. This pre-programmed feedback can also be implemented through a second group of technologies, student response systems, which include approaches like apps or “clickers” that are used by students to respond to in-class questions. The next three types of computer-to-student feedback are more sophisticated as they do not rely as much on simplistic pre-programmed responses to a choice by the student, and instead consider broader work a student has done. Automatic writing evaluation software provides guidance to students on their writing. This category includes consumer tools such as Grammarly which provides grammar guidance, as well as education-specific tools such as AcaWriter which provides task-specific guidance to students based on the rhetorical moves the student makes in their work (Knight et al., 2020). These tools are often also used in the fourth category, Computer Assisted Language Learning. The final category, intelligent tutoring systems, are a cognitivist approach that develops a model about the student based on their performance in different tasks, often multiple choice questions, and tailors future instruction and feedback to that model (Dawson et al., 2018). A general theme across these five categories is that while they can be resource-intensive to set up, they can provide useful supplementary inputs to students at scale. And as with the other categories considered, the overarching feedback design used will heavily influence their effectiveness and uptake by students.

The literature on technology and feedback for students covered thus far is almost exclusively concerned with feedback that is either provided by teachers or designed by them. A future avenue for feedback research may be to investigate the feedback processes students independently undertake. This may include, for example, consulting with peers online, paying for someone to review their work online, or uploading their work into a text-matching tool to identify any potential plagiarism.

Trust, relationships and feedback

Increasingly issues of trust, relationships, care and psychological safety are being recognized as important for motivating students to seek and engage with feedback to change behavior. In 2009, Carless (2009) observed:

Feedback requires lecturers and students to enter into a relationship of trust in which the former try to provide helpful comments that the latter attempt to use. For formative feedback to flourish it is necessary for students to be willing to reveal their own partial conceptions: in other words to invest trust in the teacher. Conversely, “faking good” (Gibbs, 2006, 26) occurs when students present themselves as knowing more than they actually do, for fear that revealing their weaknesses may be used against them (p. 82).

Teachers showing care for their students, influences their self-efficacy and effort regulation and strengthens student perceptions of trust (Price et al., 2011; Steen-Utheim and Hopfenbeck, 2019). Trusting relationships between teachers and students also influences whether students seek feedback and encourages students to talk to their tutor (Crimmins et al., 2016). “Developing positive learning relationships with personal tutors at the point of assessment feedback can encourage a sense of achievement and success at a time when students may feel most vulnerable to low self-esteem” (Cramp, 2011). Telio et al. (2016) suggest that the strength of the relationship as perceived by the student, influences how they interpret the feedback information and whether they use it. Learners were found to make sophisticated judgements about the credibility of the source of the feedback information including whether they had the student’s best intentions at heart. Students are unlikely to act on information provided by someone they perceive as untrustworthy (Telio et al., 2016).

The detrimental impact of a lack of perceived relatedness can result in students’ loss of self-efficacy, feedback avoidance and inability to use feedback comments (Ajjawi et al., 2022a). For example, Hughes et al. (2015) found that where there was minimal relationship building between students and teachers, the role of the tutor for seeking clarification was unclear. Seeing the tutor was equated with failing or having personal problems, rather than improving learning. Further, due to lack of trust, students did not want to reveal weaknesses in seeking clarification (Hughes et al., 2015). How we create learning environments of trust within our constrained and massified university “classrooms” is a fruitful area for research.

Emerging areas

The four trends identified so far (deliberate designs, feedback literacy, technology and trust) all have significant swathes of, for the most part, favorable research. In this section we highlight emerging (nascent) areas of feedback scholarship that might shape future practices and research agendas.

Supporting inclusion and diversity through feedback

We are increasingly seeing students from diverse backgrounds and with diverse characteristics admitted into and participating in higher education. Feedback is likely to be a key ingredient for the success and retention of these students. However, generally students who would most benefit from feedback often do not seek it out (Adcroft and Willis, 2013), and diverse students might also have different expectations for when and how feedback occurs. Adopting the four key messages synthesized in this chapter is likely to support diverse students, acknowledging that different approaches might be needed for different students. For example, research shows that high achieving versus low achieving students approach and use feedback information differently (Ajjawi et al., 2022a). Being explicit about deliberate and iterative feedback designs will help orient students to the goals and processes of feedback. Supporting the development of student feedback literacy capabilities will be important for engagement in feedback processes. Drawing on technology to facilitate multimedia communication can improve accessibility, and may also better account for neurodiverse students, in alignment with Universal Design for Learning (CAST, 2018). Finally, developing trusting relationships will ensure safe spaces for students who might otherwise still feel stigmatized and othered (O'Shea et al., 2016). Overall, opportunities for dialogic and interactive processes will ensure that feedback can be adapted and tailored to students' need, monitoring improvement, and ultimately supporting them to meet their learning goals. Here we clearly see feedback positioned as an opportunity to tailor the curriculum to specific students and their needs.

Internal comparisons

Further extending the idea of student-centeredness in feedback, Nicol (2021) focuses on the "internal feedback" that students generate when they compare their knowledge or performance against reference information. He argues that this process of making inner comparisons is the underlying mechanism at play in all feedback processes. In this understanding, when a student receives comments about their work from a teacher, the actual learning occurs when the student uses this information and compares it to their own knowledge and/or the work they have done. Nicol's model of feedback builds on predominantly cognitive understandings of comparison. He argues that most feedback research focuses on teacher comments, but that if we view the learning process of feedback as one of inner comparisons, we should instead broaden our focus to all information that students might use to make these comparisons.

The implications of Nicol's model for feedback practices are many. This conception of feedback as "internal" moves the field beyond typical assumptions of what constitutes feedback mentioned earlier. Viewing feedback as primarily a process of internal comparison-making and knowledge generation means that educators' roles shift from a focus on providing information to one of designing the circumstances that enable students to make comparisons between their own work and some reference information. This reference information can come from a variety of sources: teachers, peers, rubrics, exemplars, or anywhere students might glean an understanding of quality. In addition to helping students to make comparisons, Nicol also urges educators to help students make their comparisons explicit, deliberate, and mindful, for example, through requiring students to write about their comparisons. Internal feedback may also be activated through external dialogues (Gamlem and Vattøy, 2023).

Authentic feedback

When students graduate, they will continue to encounter feedback throughout their professional lives. This feedback can tend to be different from the feedback they encountered in their studies. In education, feedback information might predominantly take a written, summative form, with sanitized comments carefully crafted to avoid hurt feelings. In contrast, in workplace settings feedback information might be an angry phone call from an upset customer; frequent dialogues with a peer; or a constant stream of comments on social media. The notion of authentic feedback (Dawson et al., 2021) attempts to bridge these two worlds by considering how the feedback practices of a discipline or profession might be incorporated into education. There are five dimensions to authentic feedback in Dawson, Carless and Lee's (2021) framework: realism, which is the extent to which the educational feedback processes represent those in the target discipline or profession; cognitive challenge, which includes aspects such as problem solving and critical thinking; affective challenge, which recognizes that students need to be prepared to face the emotional challenges of workplace feedback; evaluative judgment, which involves students' understandings of quality; and enactment of feedback, which considers the obligations professional employees might have to make use of feedback. Dawson et al. argue that through incorporating these dimensions into feedback practices, educators may better prepare students for feedback in their future working lives.

Implementing authentic feedback involves analyzing the feedback practices used in a discipline or profession and considering how those might be simulated in an education setting. Doing so comes with challenges, the most significant of which relates to scaffolding. For example, first-year university students would likely find the level of affective challenge present in some workplace feedback practices to be far too high, and so they would need inauthentic supports. Authenticity is not inherently a good thing for

feedback; not all workplace feedback approaches are desirable for learning. However, by the end of a degree, students will need to be able to engage in workplace feedback without supports. A gradual incorporation of authentic feedback throughout a degree may be one way to prepare students for their future feedback lives.

An example of authentic and disciplinary feedback research conducted with software engineers, shows feedback as messages that come from the computer, and the iterative debugging processes that students undertake (Esterhazy, 2018). This is very different from what is considered as feedback in clinical placements for allied health professions students, where feedback takes place between mentors and students and is intended to promote psychological safety (Penman et al., 2021). Quinlan and Pitt (2021) summarize this by identifying two key dimensions of disciplinary feedback practices: sources and timings. The self, objects, disciplinary colleagues, and knowledge or service users can all contribute sources of feedback information and ways to interact with feedback. These contextual considerations merit investigation and may contribute further to our understanding of how and why feedback is effective, or ineffective.

Conclusion

In this chapter we have traced the many shifts and turns in conceptualization of feedback research. As can be seen multiple conceptions of feedback abound as research into feedback continues to proliferate. The multiple notions of feedback and its multiple designs may explain the heterogeneity identified in the research surrounding effects. Being clear about which conceptualization of feedback you are situated in matters. We also urge feedback researchers to engage with questions that seek to better understand when feedback works (or doesn't work), for whom, how and under which circumstances – rather than blunt “does it work?” questions. While we agree with Wiliam (2018) and Sadler (2010) that there are “no magic formulas” for the kinds of feedback that are likely to be helpful in any given situation; we do synthesize the following strategies for feedback for learning. That feedback should: (1) position students as active learners, (2) design deliberate and scaffolded iterative processes, and (3) occur within environments of trust and care. Embedding these strategies requires investment at institution, course, staff and student levels. An investment we suggest is worth the effort.

Glossary

Agency A learner's inherent capability to choose what and how to learn

Cognitive operation Manipulating information in working memory to create a particular product

COPEs A model describing main factors in a learning event: conditions that have bearing on learning, operations performed to learn, product(s) generated by operations, an evaluation of the product, standards used in evaluating the product

Declarative information Information formatted as a statement of a fact, belief or step in a procedure

Event A segment of time within which a behavior or operation happens

IF-THEN procedure A model of a learning tactic; IF particular conditions are present, THEN perform a particular learning tactic

Learning What is known; a process for adding to and modifying knowledge, beliefs and preferences

Learning strategy A pattern of learning tactics organized to guide choosing the next learning tactic based on the state produced by previously executed learning processes

Learning tactic The basic unit in a learning event whereby a particular cognitive operation is applied to particular information

nStudy A software system designed to record trace data and develop learning analytics that support learners and advance research on learning

Operational definition An explicit, unambiguous and thorough specification of conditions for reliably recording information or observing a process

Procedural information Information describing an action. When procedural information is enacted, information is transformed into a procedure

Process A sequence of events organized to achieve a goal

Self-regulated learning Exercising choice to select and adapt learning tactics and learning strategies in ways a learner believes has benefits according to the learner's standards

SMART A set of basic cognitive operations used in learning: searching, monitoring, assembling, rehearsing, translating

State A particular condition of the learner or a system at a point in time.

Trace data Information recorded about learning events according to an operational definition that provides a valid account of a theorized learning event or process

Approaches to assessing learning focus on methods for gathering, analyzing and interpreting information about two broad clusters: a learner's knowledge, and psychological factors—predominantly motivation, beliefs and affect—that moderate whether, how and what a learner learns. Assessments of knowledge and other individual differences describe the state of a learner at one point in time. For example: Does the learner know the capitol of Canada? Is the learner currently motivated to research global warming? If offered a choice, would the learner choose to study chemistry or history? Other entries in this encyclopedia comprehensively examine approaches to these conventional assessments.

Learning is also a process. Unlike states of knowledge and current beliefs or preferences, processes are dynamic. They unfold across time. In some ways, assessing learning as a process parallels assessing observable skills. Was a piano student's keyboarding of a melody correct and expressive? Was a second-language learner's use of idioms appropriate when asking for directions to a landmark? In cases like these, process are directly observable. In contrast, assessing learning as a process requires inferring latent cognitive and motivational factors.

A first step toward generating high-quality assessments is understanding what is to be assessed. The next four sections build a foundation for conceptualizing processes involved in learning. Following sections examine issues relating to assessing learning as a process.

Learning is more than what learners know

Because knowledge is a social construction, identifying what a learners knows is nuanced. Some knowledge is factual in the sense information is widely agreed to be valid or true. An example is: Water freezes at 0 °C. Other information a learner knows may be relative to a particular social frame of reference, a belief or a preference. Examples are: My university is top ranked. Statistics are always biased. Astronomy is interesting.

Instruments used in assessing knowledge conventionally present statements or tasks on paper or a computer screen. Several formats are common. Selection items include multiple-choice and matching exercises. Supply formats include fill-in-the-blank and essay items. Beliefs and preferences are typically assessed by describing a situation or presenting a claim, then inviting the respondent to select from a provided scale how strongly, how often or how similarly a description applies to them. In these cases, responses are interpreted to reflect the magnitude of an attribute at a point in time and in the context of instructions (e.g., Solve each problem to the best of your ability) or a brief description of a situation (In your economics course this semester, ...).

Assessments developed from learners' responses to these kinds of instruments represent information about the state of a learner in a particular context at a particular time. The range of states is wide. Examples include: Can a learner identify a graph of a parabola? Can the learner write the quadratic formula? Is the learner able to compute roots of a quadratic expression? Can the learner plot a parabola? Is the learner interested to investigate applications of parabolic forms in astronomy and the automobile industry? Does the learner estimate they can explain why graphs of parabolas differ?

Assessments of knowledge sometimes are based on observations of learners as they perform a task. Teachers may ask, "Please show me how you did that." A golf coach may watch a player's driving backswing. Violin teachers inspect their student's bowing. Records of behaviors made by video or audio machines often have a role in accounts of learners' states of knowledge.

In contrast to these approaches to assessing states of knowledge (or belief or preference), what kinds of information can serve in assessing how states arise or and change? What issues bear on using these kinds of information to assess learning as a process? What happens while a learner is learning? Which learning activities are effective?

A first step toward answers to these kinds of questions about assessing learning as a process is to clarify basic concepts.

States, events and processes

Data gathered using conventional assessment instruments primarily take form as factual propositions that cognitive psychologists label declarative information. Declarative information can be expressed in various formats including: definitions (Clock: an instrument measuring time.), a rule that applies if a condition is present (e.g., If temperature falls below 0 °C, water will freeze.), a list (e.g., Vowels in the English alphabet are a, e, i, o and u.), a table (Mendeleev's periodic table of chemical elements), a graph (e.g., the normal curve), and symbolic expressions (e.g., a molecule of water, H₂O; the formula for momentum, $p = mv$). Topics represented by declarative information are as broad as human experience: school subjects, interests, preferences, and motivations.

Some declarative information can be enacted. A learner can demonstrate knowledge about straight lines by plotting a graph of $y = 4x - 3$, debugging lines of computer code, finding a bus stop by following directions, safely lighting a Bunsen burner or dancing a samba. These expressions of knowledge represent a second kind of information, procedural information. Procedures almost always have two representations. In declarative form, procedures are a list of steps sometimes augmented by conditions for whether a step is taken (e.g., If the light is red, stop. If the light is green, go). When steps are enacted, the declarative form of a procedure is transformed into action.

Enacting one step in a procedure animates knowledge and creates an event. A series of events forms a process. Two key features differentiate declarative knowledge per se from events and processes. First, when a learner expresses declarative knowledge by making a selection from a computer menu, writing or typing information, that event renders observable what a learner knows, believes or prefers. Second, events can be characterized by features not applicable to declarative knowledge. One example is lag, the time between a prior event and a focal event. For instance, how long after reading an instruction to plot a parabola using a given formula does a learner make the first mark on a Cartesian grid?

Another important feature differentiates declarative information from a process. A single expression of declarative knowledge can be created by different processes. Is 11 a prime number? A learner may directly recall the answer, "Yes." Another learner may recall the definition of a prime number (a number divisible with no remainder only by 1 and by itself), test whether 11 can be divided evenly by each number between 2 and 10 and, tallying each division has no remainder, then answer "Yes." A third learner may use a search engine on a smartphone to answer, "Yes." The first two learners display the declarative knowledge through different processes. The third learner appears to know 11 is a prime number, but that may be an invalid inference. The third learner knows how to search for information but, even after answering "Yes" may not have learned 11 is a prime number. While each of these three learners expresses the same answer, the processes generating answers were very different.

To summarize, assessments of declarative and procedural knowledge involve presenting a learner with a cue and providing an opportunity for the learner to make a declaration or perform a process. Common formats for expressing declarative information are words and larger structures (sentences, essays), symbols (e.g., Na for the chemical element sodium) and structured arrangements of symbols (e.g., equations), ratings (e.g., a number selected from a provided set of options ordered on a scale) and visualizations (e.g., graphs, diagrams). Assessments of processes almost always can include declarative forms of expression. But, because a process has qualities beyond declarative expressions of knowledge, instruments for recording events and structured organizations of events making up processes typically allow gathering information about additional characteristics, such as temporal attributes.

Operational definitions

What events and patterns of events can account for learning? Answers to this question are the topics of many and varied theories of learning. Theories guide designs for instruments used to gather data, methods for analyzing data gathered and guidelines for interpreting results of analyses. Bridging from theory to an interpretation about learning as a process spans these waypoints of instrumentation, analysis and inference. A first pillar supporting that bridge answers a challenging question: How is a learning event operationally defined?

An operational definition is an explicit, unambiguous and thorough specification of conditions for reliably recording a datum. That is, an operational definition specifies how to measure something. For example, to measure a construct like effort to learn, consider this simplified case. Factors within square brackets are conditions that can be varied.

- One unit of nonsense is a consonant-vowel-consonant pseudoword (Examples are yat, bek, kib.)
- A pseudoword is displayed on a computer screen for $[d]$ seconds after which it disappears.
- Immediately after a pseudoword disappears, the computer screen displays: As rapidly as you can, please [do task t].
- At a lag of $[l]$ seconds after disappearance of the pseudoword, recall of a pseudoword is prompted with this instruction: "Please [do task r]."
- Effort will be measured by [measurement m].
- To assess effort, the measure of effort will be compared to [standard s].

Operational definitions that set a stage to measure effort can vary. One variation is the display interval, d . Another variation alters the intervening task, for example, tapping an index finger as fast as possible versus recalling words of four letters ending with the letter r (door, moor, soar ...). The recall task also can be varied, for example, "Please spell the pseudoword" or "Please spell the pseudoword backward" (yat → tay, bek → keb). The scale for measuring can vary. For example, the measurement might ask the learner to judge effort on a 5-point range anchored by "very easy" to "very difficult." For this measurement, the standard is whatever the learner chooses. Alternatively, instruments gauging dilation of the learner's pupil many measure this physiological indicator of effort (van der Wel and van Steenbergen, 2018). Standards for pupil dilation might be compared to a reference measurement of dilation when the learner views actual words, e.g., "cat" and "tan."

Each variation creates a different operational definition which reflects theoretically important differences. Theories suggest: Longer display times increase opportunity to rehearse information in working memory which increases recall. More cognitively complex intervening tasks interfere with rehearsing the pseudoword during the lag interval. Recalling the pseudoword

backward adds an additional cognitive operation beyond simply recalling the pseudoword. According to theory, each variation differently affects a learner's perception of effort or could affect the measurement of pupil dilation. A further question is how strongly the learner's subjective rating of effort correlates with effort indicated by pupil dilation, an objective measurement of effort.

This simplistic example of assessing effort to learn illustrates central issues relating to every operational definition of learning. First, what task will the learner complete and what are properties of the product(s) of the measurement of that product are proposed as evidence of learning? The example illustrates two measurements: verbatim recall and, for lack of a better label, transformed recall (recalling backwards). Both are objectively scoreable as correct or incorrect. Second, assuming unobserved cognitive events and processes are responsible for creating achievements, what does theory identify as those events and how does theory describe those events are patterned to form learning processes? Finally, interference can stymie events and obstruct or distort processes. What instrumentation will be used to observe and, if possible, quantify factors affecting whether events occur and how processes unfold? Answering these critical questions provides guidance for investigating the reliability of measurements that underlie assessments of learning as a process and the validity of interpretations about learning as a process.

Operationally defining cognitive operations and processes

A useful survey of the landscape of theories of learning is the serial *Annual Review of Psychology*, first published in 1950. Distilling the massive body of scholarship about learning as a process cannot be done justice here. With that caveat, this section introduces a typology of cognitive operations used here to set a stage for considering how to assess learning as a process.

Aspects shared among theories of learning

Excepting for the family of stalwartly behaviorist theories, which reject the scientific value of theorizing about unobservable mechanisms, cognitively-oriented theories of learning share, in varying expressions, three basic axioms. First, when learners learn, unobservable mental operations manipulate information. For example, the operation of rehearsing reinstates in working memory a practically identical copy of whatever original information is rehearsed.

Theories in the cognitive family share an assumption that learners perform operations in a hypothetical "place" in the mind called working memory. Often, but not always, operating on information in working memory increases the probability it will be stored in a second hypothetical region of memory called long-term memory. Importantly, not all information stored in long-term memory is easily or, perhaps, ever retrievable. Cognitively manipulating information in working memory does not guarantee it will be learned.

Second, no matter the topic or the format (declarative or procedural) of information, every unit of information is related to other units of information. For example, a student of chemistry knows the symbols H_2O represent one molecule of water; and the H, the O and the subscript "2" signify a water molecule consists of two hydrogen items and one oxygen atom. Information that cannot be related to knowledge stored in long-term memory is nonsense. Nonsense can be learned but not understood until it is related in some way to knowledge.

Third, an inherent property of the human cognitive system is, when one unit of information is active in working memory, other units of information related to it automatically become activated although likely with varying "strengths" of activation. The chemistry student just mentioned likely realizes the bond between the hydrogen and oxygen atoms is covalent although that fact is not evident in the symbols H_2O . Other knowledge previously learned may have less probability of being realized, perhaps that water is practically incompressible and it can have a form called heavy water, 2H_2O .

Learning happens when (a) particular units of information in working memory (b) are operated on (c) under particular conditions. One key ingredient when assessing learning as a process is operationally defining operations learners use to learn, the topic of the next section.

Basic cognitive operations

Theories of learning in the cognitive family posit cognitive operations are mechanisms that manipulate information. Because theories vary widely, the "basic" set of five operations presented here is heuristic. While this set of five operations is characteristic of theories in general, a particular operation described here may slightly misrepresent properties that make a theory distinctive. The five cognitive operations are: searching, monitoring, assembling, rehearsing and translating. They are conveniently grouped using the first letter of each operation to assemble an acronym, SMART.

Searching takes advantage of the spreading activation property of human memory by which knowledge in long-term memory that is not presently active in working memory becomes active in working memory. Usually, this is labeled recall or retrieval. To search, a learner focuses attention on one or several units of information in working memory. For example, what animal is a pet, has fur and purrs when petted? Individually, each of these standards for filtering knowledge in long-term memory is associated to a wide variety of knowledge. Attending to them as a set reduces members of that large collection to a particular product: cat.

Monitoring is an operation that compares a focal bit of information to one or multiple standards. Monitoring has two inputs: the standards and a bit of information to be examined using the standards. For example, is $y = ax + b$ a linear equation? This equation is inspected to judge whether it exhibits two properties: Is one quantity (y) equated to another (the sum of ax and b)? Does the variable quantity (x) have an exponent of 1? The product of those comparisons is a judgment: The expression is a linear equation.

Assembling creates meaningful links among bits of information to form a larger, more complex structure of information. Inputs are the bits to be assembled. The product is the new, organized information consisting of the inputs and their meaningful relationship(s). Some assemblies are simple: A sentence has a subject and a verb. Other assemblies are more complex. SMART is an assembly. A procedure to safely light a Bunsen burner can be assembled from individual steps placed in a particular serial order. A conceptual schema can assemble characteristics or properties describing a large collection of instances that vary in particular features. For example, a schema for an undergraduate student includes characteristics, or slots, such as: age, academic major, and institution of enrollment. Each slot in this schema can be filled with a unique value to describe a particular undergraduate student, a 20-year old studying educational psychology at Simon Fraser University or a 35-year old studying accounting from an online university.

Rehearsing, as noted earlier, is a cognitive operation that reinstates a practically identical copy of original information in working memory. Input is a unit of information. Output is the copy of that information.

Translating is the operation that changes characteristics of an input to have a different form. Translations preserve critical characteristics of the input and usually introduce new some new characteristics. A paraphrased sentence is a translation of the original. Because the paraphrased sentence uses different words to convey basically the same meaning, the new sentence also introduces new meaning. For example, there are nuanced differences if "This movie is disturbing." is translated "This film frightened me." Translations can change the format of information. The linear equation symbolized as $y = x + 3$ can be translated as a graph. The graph explicitly shows how the line rises at a 45 degree angle, a property not explicitly conveyed by the symbolic form (but, perhaps, readily recalled by an expert in graphing linear expressions). A procedure written as a set of instructions can be translated into a performance, as you may have experienced when assembling furniture from instructions. Listening to a ballad played by a skilled violinist invites a range of different interpretations than does reading the ballad's score.

Operationally defining a learning process

To learn, a learner applies one or a strategically arranged set of cognitive operations to information. Because cognitive operations cannot be directly observed, a first step toward assessing learning as a process is to operationally define cognitive operations. The operational definition is a bridge joining a theory about how learning happens to measurements representing learning events.

Perhaps the most readily observed event in learning is marking information. Learners everywhere highlight or underline text, circle a region in a diagram or chart, and draw an arrow pointing to a notable feature in a table or graph. To select particular information for marking, it must be distinguished from other information. We can infer from such markings the learner monitored information while studying. When particular information satisfied standards—this is important or surprising or merits further research—a mark was applied to permanently record the product of monitoring. Presumably, making this mark helps to find this special information again. Perhaps highlighted information is marked for review before exams.

Selective marking of information is an operational definition for the cognitive operation of monitoring. Input to the operation is information within the learner's purview. Output is a subset of that information that is marked.

What is missing from this operational definition is clarity about standards the learner used to monitor information for marking. Suppose after highlighting some text on the page of a textbook, a learner pens a ? in the margin near the selected text. A plausible inference is the learner experienced some confusion about the meaning or importance of information provided by the selected text. The ? is a signal about standards the learner used to monitor information. Some learners have elaborate systems for tagging selections they mark. For example, different colors used for highlighting may distinguish definitions, useful examples, and material needing additional attention to be understood. Symbols can represent standards such as confused (?), understood (✓), surprising (!) and important (*).

Cognitive operations can have multiple operational definitions, and some may involve a complex of activity and even appear counterintuitive. Consider this case: A learner using a laptop is studying a webpage about asteroids. Among other information, the page briefly mentions a category of asteroids called trojans that orbit at the L4 and L5 Lagrange points. The learner selects and copies the text "Lagrange points," pastes that selection into a search box, and presses the enter key to initiate a search of the internet for more information about Lagrange points. What do these measures imply about cognitive operations used in learning? What do they operationally define?

Selecting the text "Lagrange points" supports an inference the learner monitored this information. At this point, standards used to monitor are not apparent. The next observable event was the learner's search of the internet for more information about Lagrange points. This supports an inference about a latent process. The learner searched long-term memory for knowledge about Lagrange points, monitored what was retrieved using standards about how much was known and with what certainty, and judged prior knowledge was lacking. Because software can record these events—selecting, copying, pasting into a search box—and the exact text selected from the source and pasted into the search box—Lagrange points—it is possible to infer the what information the learner was processing.

While events comprising a learning process are measured, the precise standards the learner had in mind when monitoring are not well supported. To reveal those, the software might provide the learner with a tool to tag selections. Suppose this learner tagged the selected text “investigate.” Adding this event to the operational definition extends grounds for inferring learner’s plan: seek more information about Lagrange points to assemble with information the current webpage presents and what was already known about Lagrange points. Altogether, this pattern of measurements is an operational definition for a “small-scale” strategy for learning. Moreover, because the learner was willing to do this work, it can be inferred there is motivation to extend knowledge by searching the internet.

Complexities attending operational definitions for learning events and processes

Before describing operational definitions for particular cognitive and motivational events, it is useful to consider three issues.

Agency enacts motivation

Underlying almost all theories of learning and motivation is a subtle presumption of agency. Agency means learners have choices about how they will behave. They govern how they engage in learning by choices they make. In deciding how to engage cognitively, learners balance what they perceive are relative costs and benefits of enacting a particular choice about how to learn. Embedded in this choice are two basic motivational constructs (Bandura, 1997). An outcome expectation is the learner’s best forecast about what the product will be if a particular operation is enacted and the consequences of choosing that product as a goal. For example, does an argumentative essay sprinkled with many examples conform to requirements of the assignment? Will the instructor praise an essay with those features? An efficacy expectation is the learner’s best prediction about the extent to which (a) they have skill(s) and (b) environmental conditions allow successfully engaging processes to create that product. Building on the preceding example, a learner judges if they are skilled at creating examples.

Assuming agency in learning leads to an important corollary. How learners behave can reveal what they value—their goals—and what they are willing to do to reach goals. Thus, choices learners make about learning processes reflect motivation. Operational definitions for learning events and learning processes also are operational definitions about motivation.

Exercising agency is self-regulated learning

Because learners choose information on which they will operate and operations they will apply, the locus of learning processes is the learner. Assuming learners are rational—they try to manage learning processes to reach their goals and benefit their interests—learners are regulating their learning every time they exercise agency. Combining these propositions leads to a conclusion that learners are ubiquitously self-regulating learners (Winne, 1995a, 2018). Assessing learning as a process therefore equates to assessing self-regulated learning.

Conditions triggering operations are keys to modeling learning processes

The earlier analysis of a monitoring event hints at a subtle property of cognition which operational definitions can distort. When human beings are awake, they appear to be thinking constantly. New thoughts are triggered by changes in a learner’s environment and spreading activation that retrieves knowledge used to make sense of each instant of experience. As a result, working memory is provided a constant flow of new information from the environment, refreshed knowledge activated from long-term memory, and updates to and new assemblies involving these sources of information.

In contrast to this continuous flow of thinking, operational definitions refer to a segment of experience. Each segment corresponding to an operationally defined event is like a “dot” on a continuously updated timeline of learning processes. To connect these dots, it is helpful to conceptualize a segment as a contingency: *If* conditions in a segment have a particular profile established in the immediate past, *Then* the learner chooses operations for the next segment taking into account those conditions. This representation of thinking as *If-Then* allows modeling cognition as a flow of successive segments whereby history shapes the future.

A critical issue when designing operational definitions is whether an observer’s account of conditions correspond to conditions the learner perceives. The preceding example of monitoring is illustrative. If the operational definition did not provide a software tool the learner could use to tag a selection, an observer might misinterpret why the learner was searching the internet. By supplementing the operational definition with instrumentation the learner could use to tag the selection, the learner can reduce misinterpretations by an observer.

Conventional instruments for measuring learning as a process

Other entries in this encyclopedia comprehensively describe instrumentation, measurement protocols and analyses of measurements gathered by conventional instruments—surveys, observations of performance, and think aloud—to describe and assess learning. The next sections briefly recap material those entries provide a contrast to focusing on assessing learning as a process using computer software.

Observations

Observation systems typically provide the observer with a list behaviors. Each is labeled, e.g., “paying attention” or briefly described, e.g., “The student attends to teacher writing on the chalkboard.” Within a specific time period or within the boundaries of a learning activity, such as a lesson or class period, the observer tallies whether the behavior occurred or counts occurrences. Accounts describing variations in conditions surrounding the behavior may supplement these tallies.

After the observation period ends, a profile of learning processes can be developed from these records to indicate presence or absence of a behavior, or a count of occurrences.

Topics observed span the spectrum of labels describing cognitive, metacognitive, motivational and emotional events. Examples include: paying attention, mind wandering, judging understanding, interest and frustration. Observations may be time-stamped to allow sequencing events across the timeline of the observation period.

Distal self report: surveys

Learners can describe properties of learning processes in surveys administered on paper or by computer. Commonly, the survey begins with a description about a context the learner is to recall or imagine. Examples are; “In this course ...” or “When you study for a test” Relative to that context, items on the survey describe a learning process in behavioral terms, e.g., underlining or re-viewing a flashcard; or as a cognitive process, e.g., monitoring understanding or assembling ideas as a summary. Response formats for describing the learning process may be yes or no, or scales for rating frequency with which the process is typically applied, how important the process is in the given context, or how validly the practice describes the learner’s usual approach to learning in that context.

Almost all surveys present a set of related items, a subscale, the designer of the survey considers to represent a single learning process. Individual items on a subscale differ in what the survey designer considers superficial or incidental properties of context. For example, rehearsing with flashcards is considered the same cognitive operation as rehearsing by re-reading a paragraph in a textbook then covering it with a piece of paper. Responses to items in a subscale are summed or averaged to describe the extent of the learning process.

Proximal self report: think aloud

A think aloud protocol is a common technique used to gather data about learning processes. A learner is instructed to talk about what they think about as they engage with a learning task. Normally, learners are not coached about terms to use or what a researcher or assessor hopes or expects the learner will describe. In some research studies, participants first watch a model perform a think aloud activity or have an opportunity to try out thinking aloud in a practice context. During the learning task when the think aloud protocol is in force, it is often the case learners need prompting to continue thinking aloud while working on their task.

The learner’s uttered thoughts are recorded and transcribed. In some assessments, qualitative methods are used to find categories of learning processes, and reports are provided about the presence and relative prevalence of events and processes. In other assessments, transcripts are analyzed using a predefined system describing learning processes. Typically, instances of particular learning processes are tallied. In some cases, a timeline is developed to illustrate transitions across learning processes and to search for patterns of transitions.

Because learners rarely are experts in learning science or psychology, their descriptions usually are much less precise than experts’ wording on observation schedules and survey items. Consequently, researchers sometimes must infer what a particular learner’s phrasing means and generalize over differences in learners’ descriptions to categorize processes.

Proxies: multimodal measurements

Several technologies have gained popularity for gathering proxy indicators of learning processes. Gaze tracking equipment measures which distinct regions, called areas of interest, a learner visually inspects in an information display, the duration of each inspection and paths traversed across content as gaze travels from one area to another. Sustained inspection is interpreted as focusing attention although it is not possible to more specifically characterize how information is operated on once attended to. Paths of a learner’s gaze across areas of interest track how a learner refocuses attention and present similar difficulty in inferring operations more specifically. For example, oscillating between two areas of interest may represent monitoring information in one area of interest using information in another as a standard. Or, it may represent translating information expressed in one medium, such as text or an equation, presented in different format, such as diagram or a graph.

Measurements of a learner’s physiological states have been used to indicate intensity of cognitive processing at a point in time. Examples are heart rate, blood pressure and pupil dilation. While intensity of processing is inferred, the particular processes being engaged are not directly identifiable.

Face recognition technologies measure the configuration of several loci on a learner’s face. To develop norms, norming groups are shown images strongly expected to produce specific emotions responses. For example, an image of a large dog growling viciously is expected to produce a fear response. To infer the particular emotion a learner is experiencing in a particular context, these normed configurations are compared to a particular learner’s.

All these forms of multimodal data are time stamped. When aligned with other records, e.g., a video of screen activity on a computer, the information a learner was attending to or manipulating can be placed into correspondence with a multimodal measurement or a pattern of multimodal data. Also, a timeline can be assembled describing durations and points of transitions across constructs inferred from modal data.

Software logs and trace data

Computer software can record five basic events for constructing a timestamped record of learning processes. Four of these events are generated by a learner interacting with features of the software: clicking a feature in the software's interface, such as a button or an option in a menu list; dragging a cursor across text or diagonally across a region in an image (picture, diagram, graph) to frame it; typing text or symbols into a field; and simply moving the cursor across the display. Combinations of these events are common, e.g., clicking and holding the handle in a scroll bar, then sliding it to scroll. These events are meaningful if learners understand text labeling a feature in the software's interface (e.g., words such as *Open*, *Paste*, *Sidebar*), read and understand just-in-case documentation or just-in-time popup tooltips, and correctly interpret icons and their functions, e.g., clicking ↺ replaces information currently displayed with new information according to a developer's or author's design. The number of actions executed by the software can be extended when the learner depresses one or more modifier keys such as ⌘.

A fifth, wide-ranging class of events a computer can record are actions the software performs. For example, a tooltip may appear if the learner hovers the cursor over a feature. This is equivalent to a click event triggered by when the cursor is positioned for a specified time interval. Wikipedia uses this method to display the lead paragraph of hyperlinked pages when a learner hovers over blue styled text that is a signal for a hyperlink.

By carefully engineering software functions, labeling features and designing icons in the software interface, single events and patterns of events can trace learning processes. If data logged about events have a strong coupling to a theoretical construct, the resulting measurements are trace data (Winne, 2020). For example, in the nStudy software system (Winne et al., 2019), learners can select text or a region in a diagram, then create a tag to catalog that information. Tags can describe a type of information—e.g., example, explanation, equation—or a task—e.g., investigate, review, analyze. Tags are efficient means for retrieving information in a particular category. When a learner tags in nStudy, the software records the information selected, the tag the learner applied to that selection, and a timestamp for this event.

Tagging events trace a learning process. The click-and-drag event signals the learner monitored the information selected. The tag applied traces standards used in monitoring, e.g., information was classified as an example or meriting analysis. Assuming the learner also knows how to use tags to retrieve types of information or list reminders, tagging also signals planning about future engagement as well as motivation to apply that plan. When the tag names a task, such as review or investigate, there are strong theoretical grounds for inferring the learner has a plan for a future learning activity. For example, the tag "review" allows inferring the learner forecasts the tagged information will be important for some future task and it will not be fully or accurately recalled at that time. By tagging information, the learner offloads storage of information to the software.

nStudy: tracing learning processes using fine-grained data

To illustrate software instrumentation for gathering data about learning processes, several scenarios illustrate a learner's learning activities while using the nStudy software system (Winne et al., 2019). Fig. 1 shows two screenshots of nStudy's STUDY VIEW in a sequence spanning a few seconds of time. Primary learning activities in the STUDY VIEW are viewing and annotating information to be learned or, if a source was previously annotated, the STUDY VIEW supports review.

In the first panel, the learner is selecting information about outgassing in a comet's tail. When the learner lifts their finger from the trackpad (or stops depressing the button on a mouse), nStudy automatically displayed the left-side contextual menu listing operations the learner can apply to this selection. Not shown in the panel is a learner click on the menu option Create note. That click causes nStudy to display the right-side of the contextual menu where the learner has clicked Explore. That action causes nStudy to open the window shown in panel 2. The window is a blank form for creating an annotation. The note form is a scaffold listing slots in a schema for annotating the selected information in a way that explores its features.

This sequence of actions traces several learning events comprising a learning process. In panel 1, nStudy logs the selection of text as a trace of the learner monitoring information in this webpage. If information matches standards, THEN select it. From reading nStudy's documentation or experience with the software, the learner knows selecting the Create note option in nStudy's contextual menu will open the next menu where options for choosing a note form are available. When the learner chooses the schema for assembling information available in an Explore note, this traces standards the learner used when monitoring information selected in the webpage.

These measurements also trace motivated behavior. The learner has made specific choices among options nStudy provides. Choosing traces motivation. Performing these activities requires effort by the learner. That the learner was willing to spend effort to use tools nStudy provides traces the learner's judgment about a positive incentive associated with this learning process.

Panel 2 shows in the upper right corner of the note form the title the learner applied to this Explore note: "Tails of comets." nStudy automatically inserted text the learner selected as a hyperlink in this note. This is not a trace of rehearsing as the software,

The figure consists of two screenshots of the nStudy interface, showing a learner's study view. Both screenshots display the Wikipedia article "Comet" in the background. The interface includes a sidebar on the left with search and navigation options, and a main content area on the right where a note is being created.

Top Screenshot: The note titled "Comet" is being created. The text of the note is: "This article is about the astronomical objects. For other uses, see *Comet (disambiguation)*. A comet is an icy, small Solar System body that, when passing close to the Sun, warms and begins to release gases, a process that is called outgassing. This produces a visible atmosphere or coma, and sometimes also a tail. These phenomena are due to the effects of solar radiation and the solar wind acting upon the comet. Comet nuclei range from a few hundred meters to tens of kilometers across and are composed of loose collections of ice, dust, and small rocky particles. The coma may be up to 15 times Earth's diameter, while the tail may stretch for millions of kilometers (1 astronomical unit). If sufficiently bright, a comet may be seen from Earth without the aid of a telescope and may subtend an arc of 30° (60 Moons) across the sky. Comets have been observed and recorded since ancient times by many cultures. Comets usually have highly eccentric elliptical orbits, and they have a wide range of orbital periods, ranging from several years to potentially several millions of years. Short-period comets originate in the Kuiper belt or its associated scattered disk, and lie beyond the orbit of Neptune. Long-period comets are thought to originate in the Oort cloud, a spherical cloud of icy bodies extending from outside the Kuiper belt to halfway to the nearest star.^[1] Long-period comets are set in motion towards the Sun from the Oort cloud by gravitational perturbations caused by passing stars and the galactic tide. Hyperbolic comets may pass once through the inner Solar System before being flung to interstellar space. The appearance of a comet is called an apparition. Comets are distinguished from asteroids by the presence of an extended, visible atmosphere or coma, and sometimes also a tail." The note is titled "Comet" and is created by "nStudy".

Bottom Screenshot: The note titled "Tails of comets" is being created. The text of the note is: "outgassing. This produces a visible atmosphere or coma, and sometimes also a tail." The note is titled "Tails of comets" and is created by "nStudy". The note includes a "Project" field with the value "Project", a "Topic" field with the value "Outgassing", a "Describe what needs more research about this topic" field with the value "Parts", a "Types" field with the value "Are there different kinds, forms, categories?", a "Cause-effect relations" field with the value "Are there particular contexts/places/conditions?", and a "Context" field with the value "What are you curious about?".

Fig. 1 nStudy's Study View: a learner creates a note.

not the learner, reproduced this information. Data gathered using eye tracking gear could support such an interpretation. Other fields in the Explore note form identify slots in a schema suggesting how to explore the selected information. Light gray text in some text fields is replacement text. It is a scaffold to prompt the learner about topics or kinds of information that might be entered into each field. Replacement text disappears when the learner begins to type in a field. The note form as shown is empty except for the title and the reproduced selection. The learner is poised to assemble information with the selection by entering information into the note's fields.

At the right of the field labeled Parts is a button, . Clicking this button clones the field, adding an additional field to assemble more information in this Explore note. At the right of several other fields in this Explore note form is a button, . The learner knows clicking this button will display a message crafted by the instructional designer who authored this note form. For example, the message could be scaffolding about (a) topics or kinds of information to enter in a field and (b) an incentive, such as improving knowledge, when the learner assembles information using the note form's schema. If the learner clicks one of these buttons, the log of that event traces: (a) the learner searched knowledge about how to fill in a field, (b) monitored the product of search, judging it did not yield a satisfactory product, and (c) was motivated to seek scaffolding.

At some later time, if the learner viewed a previously filled-in note, clicking the selection which triggered making the note in the first instance will open (or switch to) the window from which that information was sourced and scroll to the selected text. This click event traces a monitoring event under conditions of the note being open plus, perhaps, other open windows displaying other information. Before clicking the hyperlinked text in this note, the learner searched knowledge in memory about outgassing. The product of that search was monitored relative to standards: Was retrieved information sufficient? Clicking the hyperlink to reinstate the source and the selection traces the learner monitoring current knowledge was not sufficient, as well as motivation to re-examine that source.

Process measurements

Records describing timestamped occurrences of learning events and patterns of events forming learning processes can be displayed in two basic formats. One is a timeline. Timelines begin with a starting event, such as a login event or a page open event, and display succeeding events on the timeline marked by the times of their occurrence. Timelines are easily interpreted to describe how events transition from one to another and the pace of learning activities. A second format shows flow of events as a graphical pattern. Graphs of learning processes are elaborated in the next section.

Assessments of learning events

Assessment has three elements: a measurement, a standard (or set of standards) to which a measurement is compared, and a judgment whether a difference(s) between the measurement and the standard(s) is (are) within allowable variation from a standard, called tolerance. Qualities of the measurement and methods that generate it, methods used to quantify differences between a standard and the measurement, and the choice of a standard and its reference framework—criterion, norm, or ipsative—each have implications for interpreting an assessment.

Other entries in this encyclopedia consider matters relating to assessments derived from observations, surveys and think aloud protocols. In those cases, although the topic assessed often will be something other than learning processes, there are few reasons or empirical grounds to expect assessments of learning processes should be understood differently because the topic of the assessment is learning processes.

Norms and specifics of reference systems can differ importantly depending on the topic assessed. Regarding normative assessments of learning processes, national norms are provided for the *Learning and Strategies Study Inventory* (LASSI; Weinstein et al., 2016), a paper-and-pencil survey for students at and above grade 6 (age 12–13). Items on the LASSI describe a variety of operations learners can apply when they study and prepare for tests. The LASSI norms are expressed as percentile rank scores for each subscale, e.g., information processing, selecting main ideas and self testing. Weinstein et al. recommend the 75th percentile as minimum score for assessing a student as proficient in a skill or competency described by a subscale. A score less than the 50th percentile is recommended as a criterion for identifying a student who may benefit from instruction or assistance in the processes described by a subscale. While there are many surveys about learning processes, norms like those for the LASSI are scarce.

Criterion-referenced assessments of learning events have been made in some research studies in which learners were trained in learning processes. For example, participants in a study investigating a reading comprehension strategy may be trained in processes comprising the strategy. After training, participants may be administered a paper-and-pencil test about the strategy or asked to demonstrate the strategy so it can be observed. To assess whether a participant in the research has developed (sufficient) skill in the strategy, the presence and sometimes qualities of component learning processes are compared to a criterion created for the experiment. Criterion-referenced assessment in this case takes a step toward providing evidence of participants' capabilities to apply the reading strategy when they read materials at a later stage in the research study. Because criteria are unique to each research study, comparing assessments across studies is difficult.

Norms and criteria have not been created for assessments based on think aloud protocols.

Norms for physiological data used in some multimodal assessments are well established owing to extensive data gathered in medical research. However, norms have not yet been related to learning processes. This can challenge the validity of interpretations of assessments unless multimodal data can be triangulated with data from normed instruments. For example, pupil dilation, elevated blood oxygen and a configuration of facial features normed to indicate surprise can converge on an assessment the learner is experiencing a surprise state. Other data, for example, trace data, would be needed to correlate that state of arousal to a cognitive operation such as monitoring or translating.

Assessments of learning processes

A learning tactic can be described as an IF-THEN sequence in which particular conditions set a stage for the learner to apply a particular operation or set of operations. For example, IF text is italicized, some learners THEN highlight it, a trace of monitoring where the standard relies on the author's interpretation of important or special information. When learning tactics are assembled into a regular pattern, a learning strategy is formed. For example, having highlighted an italicized term, IF the learner uses it to search knowledge and IF the product of search is monitored to be slight or uncertain, THEN the learner may break away to look for additional information to remedy that unsatisfying state. But, IF knowledge retrieved is monitored as ample and well-founded, THEN the learner may mark it for review and proceed with studying. The defining characteristic of a learning process that is strategic is the presence of a decision point at which one or another tactic is activated based on the status of a monitoring event.

Fig. 2 shows the flow across events in a fabricated learning process. Letters A, B ... represent distinct IF-THEN learning tactics. In this graph, one pattern of tactics observed has this sequence: A B C A B D For example, the learner selects text (A: IF text is italicized THEN select and scan for important disciplinary terms), executes a search for a term appearing in the selection (B), then annotates the selection (C) using information returned by the search of memory. The next event recorded is another selection of text (A). The learner again searches for terms in that selection (B). This time, results of the search are monitored and a different product results: information is not sufficient. So the learner tags the selection (D) to create a reminder to ask a classmate for information the search did not yield. In the lowest branch of Fig. 2, a different choice is made after the learner selects text (A). In this process, the learner monitors the selected information merits review and tags it such (E), then adds an entry in a calendar tool (F) to review items tagged for review on a particular date.

Graph representations of tactics and strategies can be assessed for several properties using a criterion referenced perspective. A tactic and a process can be assessed for its presence. However, note that a learner's failure to enact a theoretically expected tactic is ambiguous. The learner may not know conditions (IFs) that should be monitored or may have overlooked conditions. Regarding the operations (THENS), the operation(s) may not be available to the learner or the learner may not have assembled a theoretically expected operation with its triggering condition(s) to create a functioning IF-THEN production.

Assessing strategies is more complex because of potential variations in configurations of a strategy's components. Methods borrowed from graph theory (Winne et al., 1994) and process mining (e.g., see Saint et al., 2021) are available to analyze the degree to which patterns match a criterion, and to describe learning processes in terms such as their complexity and regularity. These assessments can be criterion-referenced in the sense of quantifying conformance to a canonical model for a process. Assessments also can be ipsative when a learner's current learning process is compared to earlier forms. At this time, there are no normative comparisons available to assess learner's tactics and strategies.

Psychometric issues

Reliability and validity merit attention in all assessments. Reliability is the degree to which a measurement obtained under particular conditions will replicate if that measurement is made again using the same operational definition applied under apparently identical conditions. The concept of reliability can be extended to generalizability when focus is the degree to which a measurement replicates with variation in the operational definition and/or conditions for obtaining the measurement. Validity is a claim about the accuracy and justifiability of an inference made or action taken with reference to a measurement. As is well known, reliability is a necessary but not sufficient condition for developing valid inferences.

Fig. 2 Graph representation of a learning strategy.

When assessments of learning as a process are operationalized via responses to surveys and multimodal data, following well-established guidelines generates quite reliable measurements. Other entries in this encyclopedia examine those cases. Reliability of measures of learning processes grounded in think aloud data is addressed by examining the extent to which different coders or raters generate corresponding measurements. As documented elsewhere, reliability is advantaged when operational definitions are carefully constructed and coders are thoroughly trained to apply those operational definitions.

Reliability of records marking learning events and processes when learners use software is practically perfect. It is exceedingly rare that the kinds of interactions with software previously identified are not recorded when a learner engages with software or that events are recorded when they have not happened. Nonetheless, the question of reliability of trace data is complicated. Like all human beings, learners are not perfectly reliable. They may unpredictably overlook conditions (Ifs) in which case a learning operation (Then) is not recorded. As well, they may erratically misinterpret conditions (Ifs) leading them to perform an operation (Then) inconsistently with respect to conditions. And, self-regulating learners are continually striving to develop satisfying learning processes (Winne, 1995a,b), so they purposively vary If-Then events as they explore new approaches to learning. It is not yet clear how reliability should be modeled with regard to trace data.

A critical characteristic of distal and proximal self-report data is important when considering the validity of inferences about learning processes documented by these methods. Learners' memories are imperfect and their recall can be inestimably biased by the instructions provided about how to report learning events and processes. The validity of inferences and actions referenced to self-reports about learning events and processes should explicitly recognize these measures are what learners believe they do. Beliefs are not necessarily accurate accounts about what learners do.

Regarding multimodal measurements, approaches to examining validity of inferences parallel other kinds of proxy measurements, e.g., a teacher's judgment of a pupil's knowledge or interest. These issues are thoroughly addressed elsewhere in this encyclopedia.

The extent to which trace data support valid inferences about learning events and processes is directly proportional to judgments about the degree to which the operational definition of an event or process can be judged apt in representing a proposition in the parent theory.

Conclusions

Learning is a process unfolding over a series of events as a learner searches for information in long-term memory or in the external learning environment, and operates on results those searches provide. Operations create knowledge or revise what the learner knows, believes and prefers. To model learning as a process comprehensively requires identifying conditions that initiate operations on information, kinds of operations performed, and characteristics of the product(s) each operation produces. In transitioning to the next event in a learning process, learners decide what they will do in next learning event by monitoring characteristics of operations applied, such as effort applied and pace, and properties of products those operations create, such as clarity, comprehensiveness and certitude. This self-regulated learning is modeled by the COPEs set of facets. Each facet and relationships among them are the major topics of theories of learning.

Every instrument used to gather data for measuring learning processes inherently filters records of one or several of the COPEs facets. Learners, observers and software logs all selectively and purposefully choose information to observe and measure according to a theory or perceptual model of what is important and how observations should be quantified (scaled) and analyzed. In this sense, "raw data" is an oxymoron (Gitelman, 2013).

Trace data have gained traction for measuring learning as a process. These data operationally define a specific learning process by what a learner does and the information on which a learner operates in a learning event. Operational definitions of traces avoid filtering that can distort COPEs as represented by learners' responses to survey items, think aloud protocols, observers' records of learners' activity, and multimodal data. As well, trace data are advantaged by software's near perfect reliability in capturing the population of learning events as opposed to samples gathered when other instruments are used. Assessments of learning grounded in trace data are well suited to ipsative and criterion-referenced assessment. However, there is currently a near total lack of norms when learning processes are assessed using trace data.

Introduction to the background

Tanzania including mainland and Zanzibar islands is a country of more than 50 million (National Bureau of Statistics, 2017). Rapid urbanization is a demographic trend in Tanzania and the increase in the urban population is much higher in proportion to the region's rural population. Currently, the proportion of the country's urban population grows at a rate of approximately 5% per year as compared to the national average growth rate of 2.7% (UNDP, 2015). Dar es Salaam is a rapidly expanding city and, in spite of its higher HDI score, it has within it huge disparities with acute poverty in unplanned dwellings (Lugalla and Mbwambo, 1999; UNDP, 2015). In a study of the plight of young children and youth in cities in Tanzania, (United Nations Children's Fund (UNICEF), 2012, p. 64) maintains that Dar es Salaam has one of the highest proportions of children living in unplanned settlements in sub-Saharan Africa.

According to the 1995 Education and Training Policy that applied to the standard four classes in 2017, when the research was carried out, formal education in Tanzania constituted 2 years of pre-primary education, 7 years of primary education, 4 years of junior secondary (ordinary level), 2 years of senior secondary (advanced level). Since then, an education policy 2014–15 has been introduced (United Republic of Tanzania, 2014).

The country has made strides in providing access to primary education primarily due to strong policy commitment to education since its independence in 1960, where successive governments have seen education as necessary for development. However, the quality of learning processes and outcomes is low (Uwezo Tanzania, 2013, p. 43).

Recognizing that the teacher is a significant determinant of education quality preservice teacher education was a requirement for joining the profession. All primary school teachers were required to hold a pre-service teacher qualification called Grade A teachers' certificate. An outcomes based curriculum had been introduced in the country in 2005 and updated in 2013 (Ministry of Education and Culture, 2005; Taasisi ya Elimu Tanzania, 2013). According to it teachers were expected to follow prescribed syllabus plans in each subject including mathematics syllabus. Lesson plans were written in the structure provided by the Tanzania Institute of Education (Taasisi ya Elimu Tanzania, 2008).

The teachers' college curriculum was developed by the Tanzania Institute of Education, which was also responsible for curriculum design for pre-primary, primary and secondary levels. The pre-service teacher curriculum included participatory and interactive learning as one of its objective in order to ensure that learner-centered approaches were employed by teachers. Some of the strategies suggested at pre-service teacher education and also in primary school syllabus included discussions and group work by children. The pre-service curriculum in discussing teaching of young learners noted that assessment was important for teaching and two major categories were discussed namely, continuous assessment and final assessment. The latter was conducted at the end of primary education and the responsibility of the National Examination Council of Tanzania. Continuous assessment includes all assessment that a teacher would conduct while teaching in order to determine if learners had mastered a certain sub-topic before

moving on. Ways suggested to achieve this type of assessment included tests, projects, and questions. While elements of assessment for learning may be discerned from these curricular guidelines, the concept was not used explicitly, for details see [Taasisi ya Elimu Tanzania \(2013\)](#).

The study

Assessment for learning in Africa was a 3-year (2016–2019) project carried out in selected disadvantaged school districts in South Africa and Tanzania. It aimed to generate knowledge about how to develop and sustain teacher capacity in use of assessment for improving learning in challenging educational settings.

In Tanzania the study included quantitative data from baseline and end line tests of students' performance in a specially designed mathematics test administered to more than 500 students from a purposively selected informal urban settlement in Dar es Salaam. Alongside, a teacher development program was offered to all the mathematics teachers in six selected schools as described in the forthcoming sections. This paper reports from the teacher development component in Tanzania (see also [Halai et al., 2018](#)).

Participants

The selected informal urban settlement had a total of 159 schools of which 111 were public or government owned ([Prime Minister's Office Regional Administration and Local Government, 2015](#)). Of these six were selected meeting the following criteria: (a) in low socio economic settings in urban slums; (b) with large class size class, exceeding the recommended 40:1 pupil to teacher ratio ([Taasisi ya Elimu Tanzania, 2013](#), p. 10) finally, although not a specific selection criteria for schools those working with a Teachers' College in the vicinity and serving the settlement were preferred. An assumption being that involving the teacher college in the teacher development workshop would add to the sustainability of the AfL practice introduced.

The six selected schools had class size in the range of 85–215. They were in the vicinity of a Teachers' College whose tutors were invited to all the workshops.

A brief description is provided about the demographic profile of the Mathematics teachers from the six schools showed that: All participating teachers had received pre-service teacher education; none had attended professional development in the past 3 years that was related to teaching and learning strategies; the years of teaching experience ranged from 5 to 24; the age range of teachers was from early twenties to late forties.

Teacher development

The teacher development component comprised of eight workshops aimed to: explore teachers' perspectives about learning, teaching and AfL; introduce teachers to AfL principles and practice; and engage teachers in reflection on issues arising for AfL. Thirty eight mathematics teachers and teacher educators including the mathematics teachers from the six selected schools participated in the workshops.

Additionally, twelve (12) mathematics teachers from the six selected schools were followed up with lesson observation and post-observation meetings with their mentors, analysis and evaluation of the lesson to understand issues in implementing AfL in their classroom.

Methods

A range of methods were used to collect data. Classroom observation was recorded in a specifically developed observation-protocol geared to observe key dimensions of AfL. Fieldnotes were also used and teachers were asked to write their evaluation of lessons. Interviews were undertaken with the teachers, pupils and head teachers to capture their views about teaching, learning and assessment of learning. Teachers' interviews were meant to probe issues around AfL with specific reference to issues arising during the lesson observations. At the end of the project teachers were asked to write a narrative report addressing questions such as: (i) what is your understanding of assessment for learning? (ii) How did participation in the workshop(s) shift your thinking about assessment for learning? (iii) When you used assessment for learning what were the benefits? (please give concrete examples from your practice) (iv) When you used assessment for learning what were the challenges? (please give concrete examples from your practice). Researchers involved in the process were local, trained mathematics educators, grounded in the context of primary education in the country.

Table 1 summarizes collection methods and the data generated.

Framework of analysis was mainly drawn from the works of [Wiliam \(2006\)](#) and [Hopfenbeck \(2015\)](#) as discussed below. It had the following main features:

- Students should understand what they are going to learn and what is expected of them.
- Students should get feedback on the quality of their learning and achievement
- Students should get feedback on how to take their learning forward

Table 1 Summary of methods and data generated.

<i>Activity</i>	<i>Number</i>	<i>Data generated</i>
Lessons observed (grade 4)	48	Observation schedule, fieldnotes, lesson plans, artifacts
Post-observation visits	48	Mentors' notes
Workshops	08	Workshop plans and reports
Teachers' reflection	48	Teachers' lesson evaluation, teachers' written narratives on AfL
Teacher interviews	12	Interview transcripts

- Students should be engaged in their own learning by assessing their own work and their own learning.

Research team across Tanzania and UK developed a coding scheme that was drawn from the four key principles of AfL as noted above.

Literature

Assessment for learning

Assessment in education is typically seen with a focus on outcomes in high stakes testing. Assessment of learning from such an evaluator position typically occurs at the end of a teaching unit or at the end of an academic year and is summative in nature (Brookhart, 2001). On the other hand assessment for learning is formative in nature as it is essentially concerned with how assessment can take forward the process of learning (also see Cizek and Lim, 2022).

In their large scale survey covering 404 teachers across Canada and United States to look at teachers' approaches to classroom assessment in relation to existing accountability and standards-based education DeLuca et al. (2018) maintain that more experienced teachers use more varied approaches as compared to early career teachers and go on to suggest that professional learning opportunities should be given to teachers depending upon their career stage and previous assessment education.

It could be argued that assessment for learning is an integral part of the teaching-learning process and is subsumed in it. However, learning is a complex process and depends on a number of contributory variables that play out differently for different learners. A consequence is that the same teaching sequence in a lesson may result in different learning outcomes for different students. An important consideration in the process of learning and teaching is learners' previous knowledge and experience. (Wiliam, 2011) points out that it is the process of assessment for learning that could help take into account the individual learners' needs. It is therefore important to ensure that the strategies, techniques and methods for AfL are focused upon explicitly in the teaching learning process.

In their seminal work Black and Wiliam (1998, p. 2) looked into the black box of classroom to look at formative assessment in the course of teaching and learning in the classroom and maintained that assessment becomes formative in nature when, "evidence is actually used to adapt the teaching to meet the needs of the students." Wiliam proposes five key strategies that underpin good practice in assessment for learning:

Clarifying and understanding learning intentions and criteria for success

Engineering effective classroom discussions, questions and tasks that elicit evidence of learning

Providing feedback that moves learners forward

Activating students as instructional resources for each other, and

Activating students as owners of their own learning.

Wiliam (2006, p. 8).

Along similar lines but in the context of Norway, Hopfenbeck maintains that in the Norway Education Act the main purpose of assessment is for learning based on the following principles:

- (1) Students should be able to understand what they are going to learn and what is expected of them.
- (2) Students should get feedback that informs them about the quality of their work and their level of achievement.
- (3) Students should be advised on how to improve their learning outcome.
- (4) Students should be involved in their own learning process and in self-assessment.

Hopfenbeck (2015, p. 45).

A significant element of the above principles of assessment for learning is that the onus of learning is on the students and the teachers' role is to create a facilitative environment for students' learning. This is a significant shift that would impact the dynamics of teaching and learning in the classroom (Hopfenbeck, 2018).

Teaching and learning

Kajoro (2012, 2016) confirms that teaching practice in the Tanzanian classroom is largely informed by theoretical perspectives that position the teacher in the role of a transmitter and the student in that of a passive recipient. Along similar lines, Hardman et al. (2009) profiled patterns of interaction in public schools in sub-Saharan Africa and maintained that classroom discourse in sub-Saharan African classrooms was found to be highly ritualized creating a semblance of curriculum coverage, knowledge and understanding with the most prevalent methods of teaching being teacher explanation, punctuated by a question and answer approach, choral responses, pupils copying from the chalkboard, written exercises and teachers marking pupil work and so teacher-led recitation, with its constant demand for pupil participation, ensured teachers maintained tight control of the learning environment. Halai (2016, p. 42) notes that "Classrooms in sub-Saharan Africa are often over-crowded, under-resourced, with teacher centered patterns of interaction that provide little scope for learners to discuss ideas through discussion with each other or with the teacher."

Consequently, for an Afl environment as described in the preceding section the role of teachers and students in the classroom would have to be renegotiated with concomitant shifts in the classroom pedagogic practices to empower learners to take charge of their learning. Tabulawa (2013) cautions that change in teachers' practice must take into account teachers' underpinning beliefs about the purpose of education or else the change in practice will be superficial. In an in-depth critique of reforms in teachers' pedagogic practice, he holds that imported concepts and ideas of classroom reform such as student-centered classroom' do not change teachers (and students) philosophical outlook and therefore fail to improve students' learning.

To conclude, key principles of assessment for learning support a pedagogic practice that empower learners to take their learning forward and questions the fundamental one-way didactic interactions between the teacher and the learner.

Data and results

Several key findings emerge from the data and analysis. Teachers understood assessment for learning within the normative frameworks of an outcomes based curriculum, mandated lesson progressions and examination. Second, in large classes centralized approaches to seeking evidence of learning and provision of feedback appeared to be more effective as compared to group work, which was used largely as a management strategy. Third, nature of feedback remained general and focused on the right answer.

Teachers' understanding Afl within normative context of practice

Teachers' perspective of learning was complex and reflected the understanding of learning within the constraints and possibilities of a normative context.

Assessment for learning is about knowing how one has successfully understood what he/she was required to learn and what is supposed to be improved in areas that were not well covered.

Teacher WR, School-6, Sep 11, 2017.

Assessment for learning is a process of making the pupil the major actor and major participant in the learning activity. Assessment for learning also makes the teacher not to be the chief speaker; the pupil should be the major actor and participant in his/her own learning. Thus assessment for learning does not target classes with fewer children but also assists in classes with big numbers of pupils. Assessment for learning requires the teacher to provide feedback. The feedback can be oral or written. This enables the pupil to get good responses and wide understanding in his/her learning.

Teacher TM, School-2 September 11, 2017.

The quotes above appear to put the onus of understanding on the learner and recognize that the pupil is the major actor. This is a significant insight as it reflects an understanding of teaching where the teacher is not the chief speaker. However in the reality of the classroom teachers faced certain challenges within normative requirements of outcomes based curriculum, structured lesson plans, lesson progressions and students' achievement to be evaluated in yearly examination. Content of the lesson was drawn from the

syllabus and teachers were expected to follow the sequence of progression as mandated and prepare students for the national examination:

In fact, in this new curriculum it is a lot of changes, first I desire that anything I teach should relate with coming national examinations. Also to increase the performance of children, so that's why I'm still struggling here and there to find materials, because I do not know how the examinations will look like, because we first started a new curriculum, so I get challenged, and I wish to teach what relate with the examinations in future.

Teacher SK, School-5 April 20, 2018.

Using ample time to teach a given topic so that students understand [–]. This causes me to lag behind the school plan of finishing the syllabus. Using time from other teachers teaching-period for enabling students understand better thus causing other teachers to complain that I have used part of their teaching time.

Teacher NC, School-5, September 11, 2017.

40 minutes are not enough to reach 130 students and to provide them with feedback that one has planned where and when needed[–]. The demand from the quality assurers that requires teachers to be consistent with the scheme of work (topics) that the teachers has planned to implement in a given academic year.

Teacher WR, School-6, September 11, 2017.

In the first place, my school has big numbers of students. My class has 1,099 children divided into six (6) streams namely, A, B, C, D, E and F; every stream has more than 180 students. To say the truth, it becomes very difficult for me to reach every child in the time (40 minutes) allotted for the lesson. This is the most serious challenge I face in my school. Secondly, based on the big number of students, there are some students who cannot read or write. This is another challenge in using assessment for learning.

Teacher MNj, School-4, October 24, 2017.

The above interview excerpts illustrate that teachers' perceived completion of syllabus and preparation for examination as the main purpose of their teaching. They noted the structure of a 40 min teaching period and prescribed syllabus plan posed several challenges. Teachers feel the pressure of coverage of syllabus even if their professional judgment suggests slowing down. Additional issues arise due to lack of teaching materials such as textbooks. A consequence of the requirement of strict adherence to progression was that teachers were unable to plan lessons geared to their students learning needs. Besides time, lack of materials was also a challenge that was observed and also noted by the teachers.

Seeking evidence of learning and feedback: tensions in whole class and group learning

To seek evidence of students' learning and provide feedback teachers employed three main approaches that were use of the chalkboard, group work and questioning. In practice these strategies were in the course of lessons that largely followed a three-phased structure. In the first phase the teacher introduced the topic, shared the objectives of the lesson often making reference to the previous lesson. The second phase comprised of the main body of the lesson where new knowledge was introduced and reinforced. The teacher explained a mathematical procedure or the concept using the chalkboard and this was further reinforced through group-work or other strategies. The third phase comprised of individual tasks. The teacher would write additional questions or tasks to be done in exercise books and the purpose was largely to consolidate the understanding of new knowledge. Of course there were variations and the three stages overlapped.

The three-phased lesson delivery as described above covered more or less the five elements in the prescribed lesson plan structure provided as follows: (1) Introduction; (2) New knowledge; (3) Reinforcement of new knowledge; (4) Reflection; and (5) Consolidation (Taasisi ya Elimu Tanzania, 2008). However, analysis and reflection on learning was rarely if ever undertaken as an explicit part of the lesson. In some lessons it could be seen as part of the process of the questions asked by the teachers.

Use of chalkboard

A large chalkboard along the width of one wall was found in each classroom. Teachers used the chalkboard creatively for a variety of purposes. To check the homework assignment if all students had got the questions right:

Before moving to new lesson, on the following day, we make correction on the chalkboard, given that there are some who got all the questions right, some got few. We look at every question and ask those who got the question wrong to raise their hands, you check their number, then you ask those who got the same question right to explain [...] One explains the answer and we move to other questions. Therefore, corrections and exercises enable us to understand if they understand or not.

Teacher SK, School-5, November 9, 2017.

Teachers wrote on the chalkboard exercises taken from the textbook, as many students did not have the textbooks.

Shortage of text books. I have to write questions on the blackboard every day after teaching. For instance, if I teach for 30 minutes, only 10 minutes are left for me to write the homework on the blackboard so that the students also write the questions in their exercise books. Because of this, students do not complete the work; at times, they write fewer questions on the ground that they were cleaned off by the teacher who came for the following period as he/she also needs to use the blackboard and this happens many times.

Teacher RK, School-3, September 11, 2017.

In case they assigned individual or group tasks to the students, they were invited to present their work on the chalkboard. To accommodate the demands of the large class size, in some classes two or three students would be invited simultaneously to present their work on the chalkboard divided into columns to let each students work be represented separately. The whole class was then invited to vote whether or not their peer's answer was correct but a critique of the answers was rarely undertaken.

For example, lesson observation data when simultaneous groups presented during a lesson on fractions:

Group work: The class has 8 permanent groups for discussions; two groups have eleven members while each of the other six groups has ten members.

Each group is provided with a question

Group 1: $\frac{3}{11} + \frac{4}{11}$ Group 5: $\frac{2}{9} + \frac{3}{9}$

Group 2: $\frac{4}{15} + \frac{7}{15}$ Group 6: $\frac{3}{8} + \frac{4}{8}$

Group 3: $\frac{6}{14} + \frac{5}{14}$ Group 7: $\frac{9}{30} + \frac{14}{30}$

Group 4: $\frac{2}{20} + \frac{13}{20}$ Group 8: $\frac{10}{25} + \frac{10}{25}$

The teacher goes around each group to check the progress. All the groups present their works, one presenter from each group. The teacher divides the chalkboard in to 8 sections, named the eight groups and invited each group representative to present.

All presenters present their work at the same time. After every group has written its work on the chalkboard, the teacher leads the whole class to judge the works, errors are identified and pupils are invited to the chalkboard to correct errors. For example, looking at group six's work,

$\frac{3}{8} + \frac{4}{8} = \frac{7}{8}$, some pupils claim that the work is incomplete, then the teacher invites one pupil to show the complete work on chalkboard, the pupils writes this;

showing that $\frac{3+4}{8}$ was missing in the first place

Field Observation, Teacher EO, School-1, July 14, 2017.

Data from another lesson observation highlights the difference in oral and written responses:

Generally, the questions asked point the whole class and then those raised up their hands are picked (by calling their names) to give answers. After the answers have been given, again the teacher asks the whole class to say if the answer is correct or not. If the answer is not correct, then another pupil is chosen to answer. In most cases, (orally) the incorrect responses are not discussed, what is searched is the right answer. However, when pupils are given writing tasks, the teacher is able to check and discuss with the pupils about the wrong answers, asks for clarification before asking pupils to re-do basing on teacher's comments.

Field Observation, Teacher WR, July 11, 2017.

Group work

Use of group work was observed in most of the lessons. Teachers employed group work to manage their class, draw upon more knowledgeable pupils as a resource to teach others, and also as a management strategy:

As for me I have a big challenge right now as I see pupils do not understand especially the current topic [...] I have decided that we must resume the groups because the ones who are good in numeracy will help others in their respective groups, not to mix things there are those talented pupil, they get right answers for all questions, and as the teacher you real feel happy and you see that the pupil have real understood.

Teacher IM, School-6, March 21, 2018.

By dividing students with different levels of understanding into groups and assigning them with work. Before they make presentations, they assist each other to reach consensus.

Teacher MI, School-4, September 11, 2017.

[U]sing participatory methods, dividing the students into groups they can help each other and find out that the success criteria has been easily elicited.

Teacher NC, School-5 September 11, 2017.

Teachers also used group work as a management strategy:

I have 25 students in each group, and in each group there is leadership; the chairperson and secretary, this has helped to control truancy, because it is easier to identify the absent student in a group than in the whole group of 1074, I also use the groups to build self confidence for students, it is easier for a student to present in a group of 25, and get an experience to present for the whole class, and in their presentation they alternate between the students with high ability and those with low, this helps a lot.

Teacher MNj, School-4, March 2, 2018.

While group work might have been a good strategy to manage large classes, it did raise other issues for the environment of teaching and learning and promoting learning as one field observer noted:

Due to large number of pupils, noise and other distractions were generated, since the classroom was small and did not allow many movements for pupils to attend to the activities given. As a result, the teacher spent more time in trying to stop the distractions, but the pupils did not stop until the teacher went outside and came back with a stick, she threatened to beat them. Seeing the stick, most of the students stopped making noise, however, few continued, not until the teacher called them by name.

Field Observation, Teacher IM, School-6, July 11, 2017.

Nature of feedback

Teachers often used questions to help students move forward with mathematical procedures. For example a number of multiplication tasks involving carry-over with only one digit for the multiplicand as indicated in the data:

312	144
x 5	x4
-----	-----
1560	576

Students were invited in turn to the chalkboard to present their work and the teacher asked questions in order to make explicit the process of thinking when multiplying.

T: 2 times 5 equals 10, how much do we take in head? Students chorus: 1

The above process of question and answer went on until the multiplication was complete. However, if a student made a mistake such as providing wrong multiplication facts (e.g., $4 \times 4 = 12$) she corrected the mistake but gave a general kind of feedback "she made a mistake because she does not know the tables" (*amekosea kwa sababu hajui tebo*).

Field Observation, Teacher WR, School-6, February 24, 2017.

Another example of general feedback was from a lesson on areas of rectangles:

Generally, the feedback is given by praising (words such as "Very good," "You have tried") the correct responses but for the incorrect response, areas where the mistakes occurs and how to correct are not effectively spoken to a particular pupil, instead, the teacher, either asks the whole class to prove or disprove the answer before asking another pupil to attend the same question. For example, a teacher draws the rectangle on chalkboard, 40 cm and 20 cm for length and width respectively. The she asks- "What a kind of the figure is that?", the whole class answer—"it is a rectangle."

Then the teacher asks another question- "Why?" and she picks one pupil to answer, pupil response—"because all sides are equal." The teacher says "no" and then she appoints another pupil to answer the same question.

Field Observation, Teacher IM, School-6, July 5, 2017.

There were some cases where individual pupils' mistake was used to provide a general feedback to the class by asking peers to correct the process. For example:

The third example (6 hours 25 minutes + 1 hour 35 minutes) and selected a volunteer to solve the question. The pupil made a mistake in solving and got 7 hours 00 minutes—instead of 8 hours 00 minutes—the pupil converted but forgot to "carry forward." The teacher said "I agree with [pupil's name]—anyone with a different view." Some pupils put up their hand and from those selected one comes and corrects the process. Teacher then explains the misconception to the whole class.

Field notes, Teacher TM, School-2, September 25, 2017.

Besides the feedback being very general in nature an issue was that it often did not provide the students with a guidance on how to take their learning forward. Teachers' response to questions about the nature and purpose of feedback are as follows:

For example a person answers correctly, they can clap hands for him/her, if a person answers incorrectly, One you select another one who can answer correctly; if all have failed I can explain and assign them to work in groups, they discuss within five minutes, the answer will have been found.

Teacher MNy, School-1, March 21, 2018.

First of all, if the response is incorrect I would tell her—"thanks for trying" then I would ask another child to come and assist, and if the second child misses I would ask another one, I would continue this until I get someone who would give the correct answer, [...]even if the correct answer is given [...]I would conclude by analyzing the correct answer, some of the responses may be not exactly the correct answer but close to the answer, however some of the responses are out of the topic, at times children laugh at these kind of responses, this consumes lesson time and takes time to bring them back to normal, at this stage I am force to be strict so as to maintain discipline.

Teacher WR, School-6, October 12, 2017.

The illustrative examples above show that teachers probed for feedback to elicit evidence of students' learning. However, the extent to which the information received was used to provide feedback to the students' about their learning remained a question. For instance, in the case of multiplication of money, multiplication with carry over (e.g., "holding in your head"), not knowing the tables for multiplication facts, it was not apparent if students understood the place-value of digits. Teachers identified what was the mistake or the wrong answer but there was little evidence of probing why the students had provided the wrong answer.

Conclusions and recommendations

Three main conclusions could be drawn from the data and findings in the preceding section. First, teachers predominantly saw the purpose of their teaching and their role as teachers to "cover the syllabus" and prepare students for the examinations. Second, teachers' expressed nuanced understanding of assessment for learning, the function of feedback and its implications for changes in the role of students and teachers. However, there was gap in their espoused theory and practice in relation to AfL, potentially due to several structural barriers. These include, fixed lesson structures (time, lesson plan, sequence, progression), highly prescriptive curricula, extraordinarily large classes, teachers' inadequate academic and professional preparation. Third, teachers' practice showed creative approaches to manage the large classes, provide students an opportunity to participate in the classroom and to use the work on the chalkboard as a method to seek feedback on what students' understood.

Teachers' understanding of the purpose of their practice as noted above brought to surface the inherent tension in the principles underpinning the AfL framework as introduced to them and the inherent beliefs about their practice. For example, Students taking ownership, "Activating students as owners of their own learning" (William, 2006, p. 8), or Hopfenbeck, "Students should be

involved in their own learning process and in self-assessment" (2015, p. 45) suggests that students would play an active role in the classroom and shape the dynamics through their questioning and nature of participation.

However, the observed classroom dynamics were strongly led by the teacher. Students did not initiate questions and their responses to teacher's questions remained brief. Several studies have noted that interventions in the classroom such as "Afl" are ideologically laden and cannot succeed unless the underlying beliefs and purposes of education are taken into account. For example in his in-depth work set in sub-Saharan Africa, Richard Tabulawa, looked at, why pedagogic reforms fail in sub-Saharan Africa. His maintains that aid agencies largely from Euro-western contexts, made an effort to globalize "student-centered pedagogies" from a purely technical view of education. However, pedagogic reform is theory-laden and cannot succeed through a mere technical restructuring of the education process without taking into account the historical social, political and cultural context of education (Tabulawa, 2013). Along similar lines Barrett (2007) highlights the limitations of analytical frameworks developed in western contexts applied in under-resourced education systems and proposes, a more nuanced understanding of primary school teachers' classroom practice one that would take account of teachers working with an eclectic mix of techniques and ideas. Elsewhere, in Halai and Dylan (2011) several education researchers note with clarity the challenges and dilemmas when people from one culture introduce or research education reform in the context of a very different society.

It was also noted that the teachers espoused theoretically a nuanced and complex understanding of Afl. They recognized the importance of "to understand what they(students) understand" (Teacher SK, school 5, November 9, 2017). Concomitantly, their practice also reflected an attempt to seek feedback on what the students understood or not. However, as noted earlier, the dynamics were teacher directed. Questions were posed by the teacher and almost never initiated by the students. The large class size and other normative conditions might be a factor in unidirectional classroom interaction. For example, assessment for learning would assume a differentiated pace of learning in the classroom. However, an over loaded curricula and deep concern over students' performance in examination constrained any flexibility in the teaching process. The pace of the lessons was maintained for coverage and not necessarily learning. An alternate explanation could be that the socio-cultural mores in the wider society expected children to be deferential toward their elders and not raise questions.

Finally, the practice sheds light on specific aspects that could be addressed in targeted teacher development interventions. For example, the quality and nature of feedback provided by the teachers showed that feedback was largely for "positive reinforcement" and when provided on the content of learning it was general in nature. However, for feedback to be meaningful, it must provide information on the quality of learning and achievement. It reflects the need for specific focus on Afl in teacher preparation and continuing teacher development.

To conclude, teachers largely saw their role and purpose to prepare students for success in examination. In order to progress the curriculum delivery, they employed different strategies to seek evidence of students' learning within the constraints of large class size, limited resources and a normative policy framework. However, there was little evidence of students taking ownership and charge of their learning. The paper illustrates well the tensions in introducing external frameworks of teaching and learning in socio-cultural contexts where there is a potential conflict in the underlying principles of the framework with the beliefs and practices of the teachers. It raises questions for policy and practice in improvement of mathematics teaching and learning in Tanzania and other low-income countries.

Acknowledgment

We are grateful to the field researchers in Tanzania namely, Allan Fumbo, Evodius Jackson, Naomi Katunzi, Esther Kibga, Frida Kiliwa, Rehema Mdoe, Eristine Munisi, and Kipelo Obedi for their work in collecting and recording data from the field. Grant No: ES/N010515/1 funded by ESRC UK.

A brief history of comparative judgment	73
Educational applications of comparative judgment	75
Reliability and validity of comparative judgment	76
Summary	77
References	77

Comparative judgment, also referred to as paired or pairwise comparisons, is a choice methodology that has come to prominence in educational assessment over the past 30 years, although it has a longer history in the human sciences more broadly. It is commonly argued to be a superior method for assessing complex educational constructs (e.g., extended writing skill) that are better evaluated by holistic judgments of quality rather than by rating according to a pre-determined criterion or criteria (e.g., six traits of writing rubric) or by reducing the construct to a conventionally testable form (e.g., a multiple-choice test). Moreover, it has been used as a method to evaluate and equate the comparability of different assessment tasks for a given construct across time and contexts, as well as more broadly with respect to psychological constructs such as attitudes, values, and preferences.

In essence, comparative judgment works by having a group of judges make a series of judgments on pairs of artifacts (e.g., essays, portfolios, videos, exams, attitude statements) regarding which one in the pair represents more of the construct, whether that be, for example, a higher quality of performance, a more difficult task, or a more favorable opinion. These pairwise judgments, both within and across judges, may then be scaled using a psychometric model to represent the ranking and relative differences of the different artifacts in terms of the construct.

In the following sections, I will provide a brief history of the method including its scaling, a brief overview of existing applications in educational assessment, and a discussion of the evidence for its reliability and validity in these applications. Along the way, I will provide a selection of relevant references so the interested reader may delve deeper into the methodology and its applications.

A brief history of comparative judgment

Comparative judgment was pioneered by [Thurstone \(1927a\)](#) in the field of psychophysics where it was used to elicit people's pairwise judgments regarding a physical property of a set of artifacts, e.g., which one of a pair of cylindrical weights is heavier,¹ to evaluate how people's subjective experiences of the relationships between the magnitudes of the property relate to the actual magnitudes. From this line of research, they observed that, among other things, people are better at discriminating between the physical magnitudes of the artifacts as they become more divergent, e.g., one cylindrical weight is much heavier than the other, or to put it another way, people will tend to make more errors regarding which of the two cylinders is heavier when they are similar in weight. Further, when a judge is presented with the same pair of artifacts over time, they will not always make the same judgment of which one possesses more of the property and these "switches" in judgment will occur more frequently when each of the artifacts are similar in magnitude, e.g., there will be more switches in judgment for pairs of cylinders that are more similar in weight relative to other pairs.

From these indeterminacies in the judgments, we can see how this method may be used to not only infer the perceived ranking of the artifacts in terms of the relevant attribute, e.g., how many times each cylinder was judged to be heavier than the other cylinders, but also the relative differences of the perceived magnitudes of this attribute across the artifacts, e.g., the proportion of times the judgments of the relative weight of two cylinders are switched whereby the closer this proportion is to half, the closer the two cylinders' weights are perceived to be. [Thurstone's \(1927a\)](#) seminal contribution was to formalize these observations into a model that he loftily termed the "Law of Comparative Judgment".

For a more technical yet accessible introduction to the Law of Comparative Judgment, see [Bramley \(2007\)](#), but in general terms, it involves three key assumptions. Firstly, each time a judge encounters an artifact, this interaction sets off what Thurstone termed a "discriminal process"² regarding the construct of interest, which results in a psychological magnitude for that attribute, e.g., the perceived weight of the cylinder. Secondly, this discriminial process involves what Thurstone termed a psychological continuum,

¹Note that the artifacts are presented in an experimentally controlled manner such that they are effectively identical in terms of other relevant attributes such as their size and shape.

²Thurstone invented this term to reflect his intended neutrality with respect to the actual physiological and/or psychological processes involved in the judgment process.

which is a linear continuum of the psychological magnitudes of the attribute across all artifacts, e.g., a continuum of the perceived weights of all cylinders. Finally, this discriminative process is assumed to vary across judgments whereby the perceived magnitude of the attribute will likely change each time a judge encounters the artifact, e.g., the judge will likely perceive a cylinder to be a different weight every time the same artifact is encountered, which Thurstone referred to as the “discriminative dispersion”. Moreover, this variation is assumed to be normally distributed (e.g., bell-curve shaped) on the psychological continuum, meaning that smaller differences in perceived magnitude across encounters with an artifact will be more frequent than larger differences.

Based on these assumptions, according to the Law of Comparative Judgment, the outcome of a paired comparison between two artifacts depends on both the distance between the modes (i.e., the artifact’s most frequently perceived magnitude; the top of the bell-curve) of their discriminative dispersions and the degree of overlap in these dispersions on the psychological continuum. Thus, if two artifacts have a very small modal distance and high degree of overlap in their dispersions, then there will be many switches in the judgments of which one instantiates more of the construct. In contrast, if the modal distance is large and the dispersal overlap is small, there will be very few switches. Consequently, given other simplifying assumptions, including that the discriminative dispersions are all equal and all judgments are independent, the set of comparative judgments can be used to scale the relative perceived magnitudes in terms of the proportion of times each artifact is judged to have more of the construct than the other artifacts. However, it should be noted that [Thurstone \(1927a\)](#) considered this simplest case of his model (Case 5) to be only applicable for “coarse scaling” for most applications in psychology and education. Interestingly, despite this caution, almost all contemporary applications of comparative judgment in educational research apply a scaling model known as the Bradley-Terry-Luce model ([Bradley and Terry, 1952](#); [Luce, 1959](#)), which for all intents and purposes is identical to Case 5 of the Law of Comparative Judgment ([Andrich, 1978](#)).³

[Thurstone’s \(1927b, 1928, 1959\)](#) next seminal insight was that the method of paired comparisons and his scaling “law” could also be applied to constructs for which there is no obvious physical correlate, i.e., the kinds of constructs that psychological and educational assessment routinely deal with, including social attitudes and values, and constructs more educational in nature, such as quality of handwriting and English composition (i.e., writing). He and his collaborators were particularly interested in the former two and set about compiling and scaling sets of attitude statements, e.g., sets of statements that cover the full range of possible attitudes toward capital punishment, and value exemplars, e.g., statements of different crimes that cover the range of seriousness, to create attitudes and value scales, which [Thurstone \(1928\)](#) argued could be the “yardsticks” for the measurement of these constructs.

In short, taking social attitudes as an example, the approach initially involves a group of judges making paired comparisons on large sets of attitude statements with respect to a social issue to judge which of each pair represented more of the construct, e.g., a more favorable attitude toward capital punishment. These judgments are then scaled using the Law of Comparative Judgment and distilled down to a smaller set by discarding statements that were too divergent in their discriminative dispersions compared to other statements and by selecting a subset that were clearly ordered and represented approximately equal intervals across the full range of the scale.⁴ These distilled sets of statements could then be used to assess people’s attitudes toward the social issue by asking them to agree/disagree with each of the statements and then assigning them the median scale value of the statements they agreed with as a “measure” of their attitude.⁵

Although Thurstone and his colleagues quickly compiled dozens of these attitudinal “yardsticks”, they had little long-term impact on social research and this approach almost completely disappeared from the research literature within a decade. While the reasons for this are multi-faceted, they are largely attributable to [Thurstone \(1934\)](#) quickly turning his attention to other methods in the burgeoning field of intelligence research, and crucially, [Likert’s \(1932\)](#) publication of his method of summated ratings. This method enabled attitude researchers to forgo what has been described as the “laborious and time-consuming” initial step in Thurstone’s approach of using comparative judgments (or other methods) to create the attitude scale, and instead people were given sets of pre-selected positively and negatively phrased statements about an issue and were asked to indicate their approval of them on a 5-point scale⁶ ([Edwards and Kenney, 1946](#)). Their attitude toward the issue was then “measured” by simply reverse scoring their responses to the negatively phrased statements and then summing up their ratings across all statements. [Likert \(1932\)](#) justified this approach in terms of its parsimony while also being comparably reliable to, and highly correlated with, corresponding “measures” from Thurstone’s approach.

This charge of the laboriousness of the comparative judgment approach remains its greatest criticism even today and largely led to the method being placed on the shelf in mainstream psychological and educational research for around six decades. The greatest exception to this trend was in the methodological fields concerned with human preference and choice (e.g., [Guttman, 1946](#); [Bradley and Terry, 1952](#); [Luce, 1959](#); [Coombs, 1964](#); [Andrich, 1978, 1989](#); [Michell, 1994](#)). However, in recent decades, the method has

³The Bradley-Terry-Luce model only differs from Case 5 of the Law of Comparative Judgment through its use of the logistic function, which made the mathematical calculations more straightforward prior to digital computing, but the scale scores from the two models would be almost perfectly correlated.

⁴Thurstone also applied other methods for this purpose including the method of equal-appearing intervals, which involves judges rating the statements in terms of their favorability rather than pairwise comparing them ([Thurstone and Chave, 1929](#)).

⁵In addition to an attitude measure, this approach also provides information on the individuals’ latitude of acceptance, i.e., the range of statements they agree with, their latitude of rejection, i.e., the range of statements they disagree with, and their range of non-commitment, i.e., the range of statements to which they neither agree nor disagree ([Thurstone, 1959](#); [Sherif and Hovland, 1961](#)).

⁶Despite the widespread use of the term “Likert scale” to describe a wide variety of different rating scales in terms of both number of points and category descriptors, the original 5-point [Likert \(1932\)](#) scale included the category descriptors, 1—Strongly Disapprove, 2—Disapprove, 3—Undecided, 4—Approve, 5—Strongly Approve.

undergone a renaissance in educational assessment, as it has been argued to be a reliable and valid solution for various difficulties in the field and technological advancements have helped streamline its application.

Educational applications of comparative judgment

The starting place for the revival of comparative judgment in educational research was in the context of the England's upper secondary school examination system and specifically in terms of maintaining high-stakes examination standards over time, e.g., ensuring that a "C grade" on the A-level mathematics examination in 2022 represents the same standard of achievement as the equivalent grade in previous years, as such standard maintaining is known to be affected by subjectivity and unreliability in expert judgments (Benton, 2021; Benton and Elliot, 2016; Black and Bramley, 2008; Bramley, 2005, 2007; Bramley et al., 1998; Bramley and Gill, 2010; Leech et al., 2022; Pollitt and Murray, 1996; Seery et al., 2022). Moreover, England's examination system is unique by international standards in that these high-stakes examinations are created by several different organizations, known as examination boards, which further complicates the process of ensuring comparable examination standards, as they must also be maintained across these boards. Consequently, this system has pushed research into different robust methods for maintaining these standards.

In this context, the application of comparative judgment has typically involved experts making paired comparisons of exemplar examination scripts of different grade levels from different examination years. Judges were required to make holistic judgments of which script in the various pairs demonstrated the higher standard of achievement. These judgments were then scaled to evaluate whether the ranking of the scripts mapped on to the assigned grades across years, as well as to evaluate whether scripts assigned the same grade across years substantially diverged in their perceived quality. Generally, the findings of this research have provided support for the use of comparative judgment, either in its own rights or as a complementary approach to the current official methods, to enhance the reliability and validity of expert judgments in standard maintaining (Curcin et al., 2019).

The other main area of educational research that has pushed the resurgence of comparative judgment is writing assessment, or what is sometimes referred to as essay scoring (Steedle and Ferrara, 2016). Writing assessment has been a perennial issue for education systems, as writing is a fundamental skill for students to learn, but it is typically highly resource intensive to assess reliably and validly. As a result, systems often historically either excluded it from their assessments, attempted to reduce it to its constituent parts (e.g., knowledge of grammar and punctuation) that are more readily amenable to conventional testing, attempted to standardize it using generic assessment rubrics such as the six-traits or writing rubric, or simply just acquiesced to the limitations of teacher-based assessments of writing.

Comparative judgment has been argued to be a panacea for issues related to writing assessment for several reasons. Firstly, as the method entails judgments of relative performance, it does not require assessors to rate the performances into discrete categories and so alleviates the various rater and rubric effects (e.g., rater accuracy, rater severity, central tendency bias) that are known to bias rating and rubric-based writing assessment (Humphry and Heldsinger, 2014; Wolfe, 2004). Secondly, given that comparative judgment does not require scoring pieces of writing in terms of discrete categories, it allows for more discriminating and potentially more nuanced judgments of the whole performance, and may also act as a deterrent to formulaic approaches to writing that "tick off" the criteria (Humphry and Heldsinger, 2014, 2019a). Further, McGrane et al. (2018) demonstrated how higher-level criterion judgments may be integrated into a comparative judgment framework to provide both criterion-level and combined scales to further alleviate the need for rating written performances according to discrete categories.

To date, comparative judgment has proliferated across many writing assessment contexts, including large-scale primary and secondary-level assessment (e.g., McGrane et al., 2018; Pollitt, 2012; Wheadon et al., 2020), primary-level classroom-based assessment (e.g., Heldsinger and Humphry, 2010, 2013; Humphry and Heldsinger, 2019b), higher education contexts (e.g., Lesterhuis et al., 2022; van Daal et al., 2019), English as an additional language writing contexts (e.g., Şahin, 2021; Sims et al., 2020), as well as for the longitudinal equating of a standardized writing assessment (Humphry and McGrane, 2015).

Inventive technological developments have been coupled to this proliferation of research using comparative judgment for writing assessment to help alleviate the laborious nature of the paired comparisons method (Humphry and Heldsinger, 2019b; Goossens and De Maeyer, 2017; Pollitt, 2012; Wheadon et al., 2020). These developments have primarily involved developing systems that distribute the pairwise judgments across a pool of judges in such a way that every judge only compares a small subset of them while ensuring each written performance is involved in enough comparisons for them to obtain reliable scale scores. Pollitt (2012) and colleagues add an "adaptive" component to this distribution whereby the written performances are judged and scaled in rounds, and only closely scaled pairs of performances are compared in subsequent rounds to further increase the efficiency of the judgments. Wheadon et al. (2020) allow for the "anchoring" of the scale across location and time through the inclusion of pre-scaled performances, which can also be used to moderate the judgments to ensure teachers' judgments are not biased toward their own students. Humphry and Heldsinger (2019b) adopt a two-step method, like Thurstone's "yardstick" approach, whereby in the first step, comparative judgments are used to create a scale and select a set of exemplar performances that cover the full of range of performance, and in the second step, their system has judges assess new performances by comparing them to this set of pre-scaled exemplars rather than in a pairwise manner (see also Heldsinger and Humphry, 2010, 2013; McGrane et al., 2018).

The development of such systems has additionally enabled the proliferation of comparative judgment research in areas beyond examination standards and writing assessment. These areas include using paired comparisons for predicting and comparing the

item difficulty of examinations at different education levels (e.g., Attali et al., 2014; Green, 1985; Holmes et al., 2018), for assessing students' early literacy development (e.g., Humphry et al., 2017; Pollitt and Murray, 1996), for assessing mathematical problem solving in secondary students (e.g., Jones and Inglis, 2015; Jones et al., 2015), for creative arts assessment of secondary students including digitized portfolios (e.g., Tarricone and Newhouse, 2016a,b, 2017), for design assessment of secondary and higher education students including the integration of formative assessment (e.g., Bartholomew et al., 2022, 2019; Kimbell, 2012; Seery et al., 2019), as well as competency assessment for teacher performance (e.g., Wyatt-Smith et al., 2020). As applications of comparative judgment in educational assessment grow ever broader to encompass students of all ages across various disciplines and assessments of varying stakes, the reliability and validity of the method becomes an increasingly important issue.

Reliability and validity of comparative judgment

In the context of comparative judgment, reliability is typically conceived of as the ratio of the variance in scale scores that is attributable to true differences in the construct being judged to the total variance of the scores, which includes careless judgments and other sources of uncertainty (Bramley et al., 1998; Humphry and McGrane, 2015; Verhavert et al., 2018). The typical selling point of the paired comparison method is its high level of reliability, as much of the above cited research achieved reliability indices above 0.90, indicating near perfect reliability of the scale scores. These impressive levels of reliability are typically attributed to several factors in the literature, including the highly discriminating nature of the method where judges are forced to choose between each of the artifacts rather than matching them to discrete categories, which may increase the construct-relevant variance in the scale scores (Humphry and Heldsinger, 2019b). Moreover, the relative nature of the judgments has been argued to be cognitively simpler for assessors than making categorizations when making judgments about complex constructs, which in turn enhances the internal consistency of the judgments (Pollitt, 2012).

Benton and Gallagher (2018) put forward an alternative view that comparative judgment's high level of reliability is simply a by-product of its requirement for multiple judgments on each artifact, whereas other assessment approaches such as providing a rating typically only involve a single or small number of judgments for each artifact. This conjecture is consistent with other empirical findings that have demonstrated a high association between the reliability of the comparative judgment scale scores and the number of comparisons per artifact (Crompvoets et al., 2020; Goossens and De Maeyer, 2017; Verhavert et al., 2019, 2022). A recent meta-analysis by Verhavert et al. (2019) showed that between 10 and 14 comparisons per artifact were necessary to achieve a reliability level of 0.70 and between 26 and 37 to achieve reliability levels of 0.90. More conservatively, Crompvoets et al. (2022) recommend a minimum of 41 comparisons per artifact to achieve an adequate and unbiased estimate of scale score reliability. Verhavert et al. (2019) additionally argue that the required number of comparisons will be affected by the experience levels of the judges and the specific construct being assessed.

There has recently been some controversy in the literature regarding the of comparative judgment and particularly the adaptive variant briefly described above. Bramley and Vitello (2019) show that while the use of an adaptive approach increases the efficiency of the judgment process, it also spuriously inflates the reliability statistic that is typically used to evaluate the method; in their simulation this inflation is quite dramatic from moderate to extremely high levels of implied reliability. This finding is in some ways unsurprising, as the adaptive algorithm violates Case 5 of the Law of Comparative Judgment's simplifying assumption of the independence of judgments, and the same assumption is inherent in the Bradley-Terry-Luce model. This assumption is violated by the adaptive selection algorithm because the pairs of artifacts being judged in subsequent rounds from the first depend on the pairings in earlier rounds. In the broader psychometric context, this is referred to as a violation of local independence and these violations are known to spuriously inflate the variance of scale scores, which in turn biases the reliability statistics for the scale (Andrich and Kreiner, 2010). Consequently, researchers have begun to explore other ways to increase the efficiency of the judgment process through different approaches to adaptively selecting pairs in a manner that does not inflate the scale reliability (e.g., De Vriendt et al., 2022).

In comparison to the issue of reliability, the validity of comparative judgment has received much less attention, although there has recently been a proliferation of research focused on this issue (e.g., Chambers and Cunningham, 2022; Humphry and Heldsinger, 2019a; Lesterhuis et al., 2022; Mentzer et al., 2021; van Daal et al., 2017, 2019). Typically, the method has been found to have moderate to high levels of concurrent validity with other more established methods like rubric-based ratings (e.g., Attali et al., 2014; Heldsinger and Humphry, 2010, 2013; McGrane et al., 2018). Similarly, it has been found to have moderate to high levels of criterion validity with future exam performance (e.g., Jones and Inglis, 2015; Kimbell, 2012). The most recent comparative judgment validation studies have tended to evaluate whether judges attend to construct-relevant features when comparing artifacts as well as which specific features they attend to when making these comparisons.

For example, van Daal et al. (2019) collected judges' explanations for their comparative decisions of a set of essays. After careful coding of responses, they discerned three main categories of explanation: explanations related to the assessed construct and to the construct description, explanations related to the assessed construct but unrelated to the construct description, and explanations referring to the general quality of the essays. They found that around two-thirds of the explanations referred to both the construct and construct descriptions, and very few only referred to general quality. Similarly, Humphry and Heldsinger (2019a) asked judges to indicate the extent to which ten different aspects of writing were relevant to each paired comparison they made for a set of essays of varying quality. They showed there was a sensible relationship between the aspects attended to and the level of writing being compared, i.e., judges paid attention to more basic aspects of writing like punctuation and paragraphing when comparing lower

quality writing, and higher-level aspects like ideas and structuring when comparing higher quality writing. Moreover, they provide evidence that the holistic nature of paired comparisons allowed judges to make more nuanced assessments than the rubric-derived aspects would have alone. Both studies provide positive evidence for the validity of comparative judgment and, specifically, that such judgments are made based on construct-relevant features and may even be more sensitive to construct-relevant variance than either construct descriptors or assessment rubrics are able to represent. However, to date, most of this validation research has been conducted in the context of writing assessment and so caution must be shown when drawing broader conclusions about the method.

One aspect of the validity of comparative judgment that has received almost no attention in the literature is the appropriateness of the scaling model. As discussed earlier, [Thurstone \(1927a\)](#) only considered Case 5 of his model (and by extension the Bradley-Terry-Luce model) appropriate for “coarse scaling” due its simplifying assumptions being unrealistic in most applications, yet almost every article cited in this chapter uses a variant of this model. This is even more concerning when you consider that Thurstone argued that this case of his model is more appropriate in contexts where differences in the construct are reasonably homogeneous, like when comparing the weights of cylinders, yet in the educational context, comparative judgment is often lauded as a method for scaling complex and heterogeneous constructs. The earlier example of the way violations of the local independence assumption of the model confound interpretations of the reliability of the scale scores is cautionary in terms of simply taking the scaling model assumptions for granted. Future validation research should, therefore, examine the implications of these assumptions, including how much they “coarsen” the construct of interest, and whether other models that have been developed for paired comparisons may be more appropriate (e.g., [Böckenholt, 2001](#)).

Summary

Comparative judgment has re-emerged as a mainstream approach in educational assessment over the past 30 years, and particularly in contexts where complex constructs are assessed and where expert judgment and holistic evaluation are valued to capture the nuances of the construct, including examination standard maintenance, and the assessment of writing, design, and the creative arts. Technological advancements have furthered this re-emergence by streamlining the otherwise laborious method through the easy distribution of subsets of pairs across judges, rather than requiring each judge to make each comparison, and using selective algorithms to prioritize the most informative pairwise judgments. A review of existing research has shown comparative judgment to be a highly reliable assessment method for a wide range of constructs. Moreover, it has been shown to have good validity evidence in terms of concurrent and criterion validity, as well as being highly sensitive to construct-relevant variance, although more research is required in this space. Given the proliferation of comparative judgment research in educational assessment in just the past decade, the next 30 years should prove to be even more fruitful in terms of the scope of its educational applications and further enhancement of its reliability and validity across these applications.

Introduction

Peer- and self-assessment have been widely used for some time, not only in elementary (primary) schools and high (secondary) schools and in higher education, but also in a wide range of work-place scenarios. Here we will consider peer assessment before self-assessment, but in both cases confine ourselves to formal educational environments. As the contexts are so different, elementary (primary) school, high (secondary) school and higher education will be considered separately. First, however, literature reviews or meta-analyses in each sector will be explored, although unfortunately these quite often mix studies from different contexts together without any further thought. After the literature reviews, a few specimen studies in each of primary, secondary and higher education will be discussed. The Discussion and Conclusion trace the threads of similarity between peer assessment and self-assessment.

Definitions

Peer assessment

A widely quoted definition of peer assessment refers to an arrangement for learners to consider and specify the level, value or quality of a product or performance of other equal-status learners (O'Donnell and Topping, 1998). However, other similar terms (synonyms) are in the literature (e.g., peer grading/marking—giving a score to a peer product/performance; peer feedback—peers giving elaborated feedback; peer evaluation—more usually in workplaces regarding skill and knowledge; or peer review—more usually in academia regarding assessment of written papers). Several previous studies compare two or three types of peer assessment, but the variety in types goes far beyond that. O'Donnell and Topping (1998) described a typology of relevant variables. Gielen et al. (2011) offered a more developed inventory. Further developments came from Topping (2018), outlining 43 variables.

Self-assessment

Self-assessment can be defined as the involvement of learners in making judgments of merit or worth about their achievements and the outcomes of their learning—identifying standards and/or criteria to apply to their work and making judgments about the extent to which they have met those criteria and standards (Boud, 2013). Brown and Harris (2013) defined self-assessment as an “evaluative act carried out by the student concerning his or her own work and academic abilities” (p. 368). Panadero et al. (2016) defined it as a “wide variety of mechanisms and techniques through which students assign merit or worth to (i.e., evaluate) the qualities of their own learning processes and products” (p. 804). Andrade (2019) offered: “Self-assessment is the act of monitoring one’s

processes and products in order to make adjustments that deepen learning and enhance performance” (p. 10). As with peer assessment, clear criteria are crucial, and these may be developed with students in discussion or simply inflicted upon them (the latter option yielding worse results).

Theory

Theory of peer assessment

Peer assessment is not just for managing assessment burdens for teachers, but more importantly a mechanism for learning, particularly when incorporating elaborated feedback. For the assessor, the intellectual demands of reflecting, making a balanced assessment, formulating and delivering feedback can all lead to learning gains (Yu, 2011). For the assessee, the intellectual demands of receiving and evaluating the feedback, deciding what aspects to implement and what not, and reflecting on other issues prompted by the feedback but not contained within it can all lead to learning gains (Li et al., 2012). A more comprehensive and integrated theoretical model was proposed by Topping (2018), encompassing: organization and engagement; cognitive conflict; scaffolding and error management; communication; affect; re-tuning and inter-subjectivity; practice and generalization; reinforcement; meta-cognition, self-regulation and self-efficacy; and levels of learning. This indicated many of the processes which may or may not occur during PA.

Theory of self-assessment

By contrast, self-assessment has been relatively under-theorized, although Boud (2013) considers it at some length. Perhaps the most useful theoretical analysis comes from Panadero et al. (2019), who discuss the role of developing evaluative judgments in self-assessment and relate this to two models of self-regulated learning (those of Zimmerman and Winne). Zimmerman’s model mentions motivation, attention focusing and self-efficacy, while Winne’s model mentions motivational issues but is more cognitive. Andrade (2019) comments that formative self-assessment can promote knowledge and skill development, but that this is not surprising, given that it involves many of the processes known to support learning, including practice, feedback, revision, and especially the intellectually demanding work of making complex, criterion-referenced judgments.

Reliability

It is often assumed that teacher “expert” assessment should be the criterion for validity, but several studies show that peer assessment is more reliable and effective than teacher assessment, although teacher assessment is not very reliable (e.g., Johnson, 2013). The relationship with teacher assessment is better described as “consistency” rather than “accuracy”. There are similar effects at primary school, secondary school and in higher education. Likewise, for self-assessment, Ross (2006) found that it produced consistent results across items, tasks, and short time periods and contributed to higher student achievement and improved behavior, while corresponding only in part to teacher assessments.

Online or face-to-face

Self-assessment can of course be an endeavor conducted in isolation, although arranging for students to buddy with others to reflect jointly is a useful practice. Peer assessment is by definition more complex, and particularly when applied to large classes in higher education, it can become difficult to manage. Having peer assessors and assessees meet online at a time of their choosing (whether synchronously or asynchronously) gets round these problems. Another advantage of online peer assessment is that it can easily be made anonymous, so students will not know who is assessing them, and this may encourage their responses to be somewhat more critical than they would otherwise be, at least in the early stages. Developing trust with someone you may never have met and who remains anonymous can be a challenge, so often social and trust-building activities are built into initial training, and/or anonymous peer assessment is used only for the first stages of the project (Castle and McGuire, 2010). There are also software systems for managing peer assessment on a large scale, which allocate assessors to assessees, collect the assessments, and average out assessments in small groups of students who mutually assess.

Peer assessment

Literature reviews

There have been many literature reviews on peer assessment which have all been positive, from the earliest reviews (e.g., Topping, 1998, on peer grades and feedback; Falchikov and Goldfinch, 2000, on peer grades) to the latest meta-analyses. A systematic literature review on peer assessment was reported by Van Gennip et al. (2009). Fifteen studies 1990–2008 dealt with effects on achievement. However, only one of these studies included students from a school (a secondary school); the remainder consisting of university students. Peer assessment had positive effects. The authors developed four underlying constructs: psychological safety, value diversity, interdependence and trust. Psychological safety was defined as a belief that it is safe to take interpersonal risks in a group of people or the extent of confidence in the rest of the group. Value diversity referred to differences in opinion about what a team’s task, goal or mission should be—it should be low for peer work to be effective. Interdependence has been long

studied, but needed to be perceived by the participants rather than assumed by teaching staff. Several studies noted that students felt uncomfortable criticizing one another's work, or found it difficult to rate their peers, at least initially. [Tillema et al. \(2011\)](#) considered what quality criteria were specifically relevant to peer assessment. One hundred and thirty-two studies of peer assessment were analyzed. Where emphasis was placed on authenticity and future learning needs across the lifespan, peer assessment showed positive effects in terms of generalizability, and particularly utility in contexts beyond the present institution.

[Li et al. \(2016\)](#) meta-analyzed studies on peer assessment in digital platforms (mainly in universities) from 1999 to 2015, finding an average correlation between peer and teacher ratings of 0.63—moderately strong. In further meta-analyses, [Li et al. \(2020\)](#) found an overall Effect Size of 0.29 in 58 studies (Effect Size [ES] is a quantitative measure of the strength of the relationship between two variables which is independent of any measures and free of any units—the larger the ES the stronger the relationship). There were significant moderator variables of Training & Online/Digital (Moderator Variables are third order variables that affect the size or nature of the relationship between an independent and dependent variable). [Double et al. \(2020\)](#) found an overall ES of 0.31 in 54 studies, but no significant moderator variables. There are issues here about replicability – were the studies and analyses the same in the two papers?

[Zheng et al. \(2020\)](#) meta-analyzed 37 studies of computerized peer assessment from 1998 to 2018. Technology-facilitated peer assessment had a significant and medium mean ES (0.58) on learning achievement. The use of extra supporting strategies had a similar ES (0.54). Moderator variables such as training for assessors, duration and grouping types were related to effect sizes. A review of fifteen studies of peer assessment in teacher education from 2002 to 2020 was offered by [Cabello and Topping \(2020\)](#). Various types of peer assessment were used but overall peer assessment was found to be effective. Theoretical perspectives were reviewed and practical implications for decision-makers highlighted.

Elementary school

[Lin et al. \(2006\)](#) reported the successful use of a web-based portfolio for peer assessment for visual art education in elementary school. The peer assessment component helped the students' learning and the web-based portfolios helped teachers assess student learning progress. [Harrison et al. \(2015\)](#) found that teacher assessment worked against the self-reliance development of students and used peer assessment with 523 students. During self- and peer-assessment, students developed skills as critical and creative thinkers, effective communicators and collaborative team workers, becoming more personally productive and effective. Their self-awareness and self-reflection increased significantly. All of these were essential components of self-control and self-direction. [Boon \(2016\)](#) studied children's uptake of feedback during peer assessment in primary school writing. Findings showed that pupils made better use of feedback if: it was task-involving and useful; there was sufficient time given for them to act on it and discuss it with their peers; and they were asked to reflect on how it had been used to improve the quality of the assessed work.

Two studies examined the efficacy of different methods of applying peer assessment. [Yang et al. \(2005\)](#) developed a web-based interactive writing environment in a 2-year longitudinal study. Peer assessment was used to provide constructive comments to foster students' ability to review and criticize other writers' essays, to enable students to review their own essay, and to encourage students to improve their writing skills. Students who participated submitted many essays, interacted with other students online, and reviewed other essays, improving their writing skills. By contrast, [Chin and Teou \(2009\)](#) used concept cartoons with two parallel experimental classes of younger (9–10-year-old) and older (10–11-year-old) students. The cartoons presented opposing viewpoints about scientific ideas to stimulate talk and argumentation among students in small peer assessment groups. The dialogic talk and interactive argumentation of the students provided diagnostic feedback about students' misconceptions about scientific principles to the teacher, and was helpful in moving students toward better understanding.

Students who score high on academic achievement are more accepted, less rejected and disliked by peers, viewed by teachers as less deviant, and engage in more positive interactions than those who score low (e.g., [Malecki and Elliott, 2002](#)), which may suggest that able students would make the best peer assessors. However, [Bryan's \(2005\)](#) research demonstrated that certain types of social skills interventions (particularly those focused on self-perceptions, self-attributions and locus of control) had consistent positive effects on academic achievement, as did peer assessment, through which it was possible to raise the self-esteem and social-connectedness of rejected children and also raise their academic achievement.

[Rockhill and Asher \(1992\)](#) examined the types of behavior that distinguished between low-accepted children and their better-accepted classmates. Third-through fifth-graders ($n = 881$) in five elementary schools completed a sociometric scale and a peer nomination measure. The same behaviors were important for boys and girls. Both aggressive and withdrawn children received lower peer ratings for prosocial behavior, and these were less popular as peer assessment partners. [Yurdabakan \(2011\)](#) studied 46 fourth grade (aged 9–10) participants (28 female, 18 male) in a social sciences course. Students scored their same and opposite sexes with respect to their contribution to group work and their learning levels. The consistency between female student and teacher scores was higher than male student and teacher scores (the teacher was male). Peer assessment has been also used successfully with special needs children (e.g., [Scruggs and Mastropieri, 1998](#)), with students as young as grade four (9 years old). Importantly, there were gains from functioning as either assessor or assessee. Studies in this category also have implications for matching students involved in peer assessment.

Turning to more recent research, [Colognesi et al. \(2020\)](#) sought to understand which form of peer assessment was most effective in helping pupils progress with their speaking skills: when the peers discuss their feedback in subgroups or when they provide it individually in writing. Their total sample was 42 pupils aged 10–11 years from the same school. The discussed oral feedback condition was the most effective, and included more suggestions for action. [Hwang and Chang \(2020\)](#) developed a bi-directional

peer-assessment-based concept mapping system, which engaged students in assessing peers' concept maps and evaluating peers' ratings and comments. They tested this with 101 fifth graders from four classes, one condition adopting the bi-directional peer-assessment approach, while the control group adopted the conventional peer assessment approach for concept mapping. The bi-directional system increased learning achievement and the completeness of concept mapping, and also enhanced their critical thinking and the feedback quality of the peer assessment. [Chang et al. \(2020\)](#) developed a peer assessment approach incorporating virtual reality (VR) into design activities with fifth-grade natural science students. All the students were asked to design a VR project. From two conditions, one with peer assessment and the other with teacher feedback, data was collected on learning achievements, learning motivation, self-efficacy, critical thinking, creativity, and cognitive load before and after the activities. The peer assessment group showed higher learning effectiveness, and higher self-efficacy and critical thinking tendencies.

High school

In Taiwan, [Sung et al. \(2005\)](#) used progressively focused self- and peer assessment procedures with students developing designs for new websites. Two classes of 76 14–15-year-olds of above average ability assessed random websites produced by their peers. Self-assessment preceded peer assessment. The quality of the students' performance improved only after the peer assessment activities. [Tseng and Tsai \(2007\)](#) found that 184 10th grade 16-year-old students significantly improved their projects for a computer course by engaging in successive rounds of peer assessment activities. The study also related the type of peer assessment feedback (reinforcing, didactic, corrective or suggestive) to subsequent performance in the student projects. Reinforcing peer feedback was useful in the development of better projects. Suggestive feedback was helpful at the beginning of peer assessment. However, didactic feedback, and to an extent corrective feedback, were negatively correlated with student achievement. Similarly, [Chang and Chou \(2011\)](#) examined the effects of reflection quality in peer assessment with 45 14-year-old students during a web-based portfolio process. The immediate influence of reflection quality on learning outcomes was small, but positive and statistically significant. Follow-up found reflection quality significantly related to scores on an achievement test, work, and attitude outcomes.

A Belgian team ([Gielen et al., 2010](#)) examined the effectiveness of certain characteristics of peer assessment feedback in a quasi-experimental, repeated measures study of 43 13-year-old students. Written assignments showed that receiving justified comments in feedback was related to improvements in writing performance, but this effect diminished for students with higher pre-test performance. The effect of accuracy of feedback was less than the effect of justification. [Sung et al. \(2010\)](#) explored peer assessment in individual music performance with 116 seventh graders. Then 110 eighth graders had student-constructed web pages subject to peer assessments. Reliability and validity increased with the number of raters in both studies. Low- and high-achieving students tended to over- and underestimate the quality of their work, respectively.

[Lu and Law \(2012\)](#) studied 181 high school students engaged in online peer assessment. Peers graded and gave feedback, which was analyzed. Lu and Law found that provision by student assessors of feedback that identified problems and gave suggestions was a significant predictor of the performance of the assessors themselves, and that positive affective feedback was related to the performance of assesseees. [Hsia et al. \(2016\)](#) used a web-based peer-assessment method for performing arts activities, applied to 163 junior high students (experimental group and control group). Controls learned with a web-based streaming video-supported environment. Peer assessment using a rubric significantly improved the students' performance, self-efficacy and motivation. Performance ratings were highly related to the students' self-efficacy. Students who learned with peer assessment were significantly more satisfied with the learning activity than controls.

More recent research has tended to focus on more developed kinds of information technology. Thus, [Chien et al. \(2020\)](#) used a spherical video-based virtual reality environment to situate English as Foreign Language students in authentic English-speaking contexts, and coupled this with peer assessment to have students provide feedback to peers and also reflect on their own performance. Comparing peer assessment with non-peer assessment conditions showed the former was superior in terms of English speaking, learning motivation and critical thinking skills, as well as reduced anxiety. Praise feedback was positively correlated with performance.

Higher education

Peer assessment in teacher education was investigated by [Sluijsmans et al. \(2002\)](#). Ninety-three pre-service teachers were randomly assigned to control and experimental groups. Experimental groups were trained in defining performance criteria, giving feedback and writing assessment reports, through peer assessment tasks embedded in a course. Analysis of assessment reports written by students showed the experimental group surpassed the control group in quality of assessment skill. Experimental students also scored significantly higher on end products of the course. [Strijbos et al. \(2010\)](#) worked with graduate students in the context of peer assessment of academic writing, investigating the impact of various types of feedback and the sender's competence level. Students were assigned to four experimental groups and a control group. Experimental groups received a scenario with either Concise General (CGF) or Elaborated Specific (ESF) feedback by a high or low competence peer. ESF by a high competence peer was perceived as more adequate, but led to more negative affect. Overall, CGF groups outperformed ESF groups. Sender's perceived competence clearly affected student perceptions and should be taken into account.

[Cho and MacArthur \(2010\)](#) worked with undergraduates who received feedback from a single expert, or a single peer, or multiple peers. Students receiving feedback from multiple peers received more feedback of all types (directive, non-directive, and praise). Students in the multiple peers group revised their work better than other groups, largely as a result of non-directive feedback.

This study clearly showed that students performed better with feedback from their peers rather than with feedback by an expert. New technology was used by [Chen \(2010\)](#), who developed a Mobile Assessment Participation System (MAPS) using Personal Digital Assistants (PDAs), which enabled more flexible assessment arrangements, more efficient use of time, and more opportunities for student reflection. Thirty-seven teacher-education students participated, using MAPS over two rounds of assessment for self- and peer assessment. Scores obtained from the assessment activities confirmed the benefits of MAPS. However, the students were still concerned over the objectivity of peer assessment and the difficulty of providing constructive feedback.

University freshmen studying English as a Foreign Language were involved by [Van Steendam et al. \(2010\)](#) in either observing or practicing higher-order peer feedback, in the hope that subsequent emulation would be more efficient for the quality of revision. If emulation took place individually, then observation and practice were equally effective for strategy acquisition. However, for dyadic emulation to be productive, it needed to be preceded by observation. Thus, the effectiveness of each instructional format was influenced by whether the students worked individually or in dyads. [Jones and Alcock \(2014\)](#) had 1st year mathematics undergraduates ($N = 194$) judge pairs of scripts against one another in the absence of assessment criteria, i.e., pairwise comparative judgment. The students performed well as peer assessors despite the absence of assessment criteria.

Developing critical thinking in a context which did not favor this among Hong Kong undergraduates was carried out by [Zhan \(2020\)](#). Elements of the program included: online peer assessment training, provision of guiding questions, peer feedback requirements, anonymity, student evaluation of the usefulness of peer feedback and summative use of online peer assessment. E-journal entries revealed a significant improvement in critical thinking in the experimental groups. This study highlights the need to adopt a culturally embedded approach to design online peer assessment for cultivating critical thinking in non-western contexts. [Hsia and Hwang \(2020\)](#) used a mobile technology-assisted peer assessment approach over 15 weeks in a university dance choreography class of 266 students, divided into experimental and control groups and involving two rounds of peer assessment. The results showed that mobile peer assessment could significantly enhance the innovative competence of dance routines and dance skills. In addition, the students felt mobile peer assessment could assist them in understanding accurate evaluation criteria, reflecting in a more objective way, and broadening aspects of appreciation.

[Lai et al. \(2020\)](#) worked with 100 4th-year nursing students in Taiwan divided into experimental and control groups, implementing a web-based video-annotation system supporting two rounds of online peer-assessment activities in a nursing communication training scenario. The control group added comments using YouTube, which also has video-annotation capabilities. Effects on communication skills and professional attitudes were considerable—the video-annotation tool notably enhanced nursing students' communication performance. Students using the tool provided more suggestions than those who did not use it. An online peer assessment learning platform involving viewing of videos of others' performance was integrated into a musical theater course in a university in Taiwan by [Chen et al. \(2020\)](#). There were three peer assessment modes, namely peer scoring, peer commenting, and peer scoring and commenting. Three classes of students each used one of the three different peer assessment modes. The students who learned with the peer scoring and commenting mode improved their performance; in addition, they provided more critical feedback and read the rubrics more, watching example videos, watching peers' work, and reading peers' feedback. Students who learned with the peer scoring mode evaluated more peers' works, but showed few behaviors regarding viewing others' comments or reading the rubrics.

Self-assessment

Literature reviews

An early systematic review was conducted by [Sebba et al. \(2008\)](#), who found that self-assessment improved pupil attainment across a range of subjects (9 out of 15 studies) and pupil self-esteem also increased (7 out of 9 studies). There was increased engagement with learning, especially goal setting, clarifying objectives, taking responsibility for learning, and/or increased confidence (17 out of 20 studies). Teachers needed to be able to foster an interdependent relationship between teacher and students. It seemed to be important to involve students in "co-designing" the criteria for evaluation. Seven studies identified the need for students to receive some training in self-assessment.

A subsequent meta-analysis found the impact of self-assessment on achievement to have an ES of 0.40–0.45 ([Brown and Harris, 2013](#)), but with great variability. The authors argued that it was a form of self-regulation, a principle that was to become increasingly popular in the future. A further meta-analysis gave strength to the influence of self-assessment interventions on self-regulated learning with ESs of 0.23, 0.65 and 0.43 on three different measures of self-regulated learning and also an ES of 0.73 for impact of self-assessment on self-efficacy, a crucial self-regulatory feature ([Panadero et al., 2017](#)).

[Andrade \(2019\)](#) reviewed 76 empirical studies 2013–2018. Of these, 44 focused on the consistency of student self-assessment with other judgments, 25 investigated the relationship between self-assessment and achievement, 15 explored students' perceptions and 12 focused on the association between self-assessment and self-regulated learning. Of the studies of achievement, 20 focused on formative self-assessment and all of these demonstrated a positive association with learning. Treatment groups outperformed their comparison or control groups in everything from writing to dart-throwing, map-making, speaking English, and exams in a wide variety of disciplines. However, none of these papers discriminated between primary, secondary and higher education, and participants were from Grade 1 through to pre-service teachers and nurses.

Primary school

Self-assessment has formed a large part of the Scottish Government's push toward formative assessment, particularly in the context of the "Assessment for Learning" initiative. [Kirtan et al. \(2007\)](#) reported on an evaluation in 12 Scottish primary schools. Data from pupils, teachers and parents showed pupils taking more responsibility for their learning, contributing to improved motivation, confidence and classroom achievement, especially for lower attainers. Teachers and pupils in all schools provided evidence of real change in teaching and learning practices, involving changes in concentration, attainment, quality of work and learning skills. Self-assessment was associated with enjoyment and increased motivation of pupils, whereas pupils' attitudes to national summative tests indicated fear and loathing. The initiative also moved some teachers from a teacher-centered pedagogy to one which was more student-centered.

In the USA, [Andrade et al. \(2008\)](#) scaffolded self-assessment by having 116 grade 3 and 4 students read a model written assignment, generate a list of assessment criteria and use a rubric to self-assess first drafts. Evaluation considered time spent writing, prior rubric use and previous achievement. A comparison group generated a list of criteria for an effective story/essay, and reviewed first drafts, but did not self-assess. The experimental group gained significantly more than the comparison group, and the more the rubric was used, the better were the outcomes. Using a model and rubric seemed to be effective in helping students produce better writing. A further study by [Andrade et al. \(2010\)](#) investigated 162 students using a model essay, generating criteria and self-assessing first drafts with a rubric in relation to writing assignments. The comparison condition again involved generating a list of criteria and reviewing first drafts. Findings included main effects of treatment, grade level, writing time, and previous achievement on total essay scores, as well as main effects on scores for every criterion on the scoring rubric. Using a rubric helped students produce more effective writing.

Turning to Ireland, [Keane and Griffin \(2018\)](#) sought to investigate whether 85 children's academic self-assessments became more accurate in line with increased age and higher prior literacy attainment. Children from Grades 2, 5 and 6 wrote an English essay then self-assessed their work using rubrics. Children's self-assessments became significantly more accurate in line with increased age. Strong correlations also emerged between higher prior literacy attainment and children's accuracy in self-assessment. Primary school children with low literacy attainment displayed some difficulty making accurate self-assessments of their academic work in literacy, but this improved with age.

How might self-assessment work in a country where highly teacher-directed education was the norm? [Yan et al. \(2020a\)](#) report on a study with 1425 students in Hong Kong. Self-efficacy and perceived controllability were statistically significant predictors on intention to self-assess, while self-efficacy and intention had a significant influence on self-assessment practice. Psychological safety also had a significant impact on both self-assessment intention and practice. The role of self-efficacy here is clearly important, and is closely connected with that of psychological safety. Taking on individual responsibility in a situation where that responsibility has formerly rested completely with the teacher obviously requires considerable self-confidence—which teachers have to foster if self-assessment is to be effective with all students. Also recently, [Falk et al. \(2020\)](#) found that children from high socioeconomic status (SES) families were more accurate in their self-assessment compared to children from low SES families. The children were then engaged in a mentoring program designed to enhance their self-assessment skills, which had a positive effect on the accuracy of self-assessment, and the mentoring program was most effective for low-SES children.

Secondary school

[Kostons et al. \(2012\)](#) modeled engaging in self-assessment and task selection with 80 students. A second experiment with 90 students showed that providing examples and practice further enhanced student performance at self-assessment. Self-assessment and task-selection skills could play an important role in self-regulated learning and training these skills could significantly increase student performance. The effects of two different self-assessment supports—rubrics and scripts—on self-regulation, learning and self-efficacy were investigated with 120 geography students by [Panadero et al. \(2012\)](#). Self-regulation was measured through questionnaires and thinking aloud protocols. The results showed that the use of rubrics and scripts increased learning over the control group, and that scripts enhanced self-regulation more than rubrics. [Fastre et al. \(2012\)](#) worked with 68 nursing and care students involved in self-assessment. One group had all possible assessment criteria while the other had the most relevant criteria highlighted. Students in the highlighted group outperformed the others, including in generating more points of improvement, but they experienced higher mental effort in self-assessing their performance.

In Taiwan, [Chang et al. \(2013\)](#) explored the reliability and validity of Web-based portfolio self-assessment with 72 students enrolled in a computer applications course. They created learning portfolios, viewed peers' work, and twice performed self-assessments on the web-based portfolio assessment system. The results showed that: (1) there was high consistency between students' two assessment results; (2) self-assessment and teacher-assessment results were highly consistent; (3) the results of self-assessment and end-of-course examination were highly consistent. This implies that web-based portfolio self-assessment accurately reflects learning achievements, and is a reliable and valid assessment method. In Indonesia, [Ratminingsih et al. \(2018\)](#) used self-assessment in teaching English as a Foreign Language, investigating the effect of self-assessment on students' independence and writing competence. The effects of self-assessment on writing texts in three separate genres was explored, while a control group received a traditional teacher assessment. The outcome measure was a writing competence test, and student opinions were also sampled. On both measures a positive effect was evident. Teachers were recommended to promote the use of self-assessment to improve student independence and writing competence.

Groenendijk et al. (2020) used a visual rubric for assessing production and reception activities in art education. Students appreciated the rubric's visual form. It was not found that students, or boys in particular, overestimated their own performance in art education. Yan et al. (2020b) were similarly innovative, using a self-assessment diary intervention with 74 12-year-old students to explore effects on academic achievement, self-regulation and motivation. After each homework assignment, the intervention condition used the diary while the control condition did not. Self-assessment diaries significantly enhanced students' academic achievement, self-efficacy, and intrinsic value. Students with lower past achievement benefited more than other students from the intervention.

Higher education

Mort and Hansen (2010) used video review to heighten 1st-year undergraduate students' ability to self-assess communication skills. Students participated in a video-recorded counseling-simulation exercise, completing self-assessment before and after viewing their video. The largest portion of the students overestimated their skills in comparison to faculty member's evaluations, but video review brought about an increase in the self-assessment scores for nearly two-thirds (62%) of the students. It was argued that there should be opportunities for students to develop self-assessment skills early, and this should be reinforced throughout the curriculum. The gender perspective in student self-assessment was investigated by Torres-Guijarro and Bengoechea (2017) in three different courses across several academic years in an engineering school in Spain. Previous research demonstrated sex differences in self-image and self-confidence, both closely related to self-esteem and same- and other-sex esteem. Thus, gender effects might be expected in self-assessment, which is closely linked to self-image and self-confidence. The results indeed showed that women judged themselves too harshly.

Self-assessment is said to be related both to academic achievement and self-regulated learning (SRL). With 63 students enrolled in a 1-year teacher education master's program, Yan (2020) investigated the characteristics of self-assessment practices at different SRL phases and their relationship with academic achievement. The participants conducted four self-assessment actions at the SRL Preparatory, Performance and Appraisal phases. Final scores on the assignment showed that self-assessment was a fundamental skill for SRL and occurred at each SRL phase with different patterns. Self-reflection at the Performance phase was found to influence feedback seeking at the Appraisal phase. Self-directed feedback seeking was the strongest and most positive predictor of academic achievement. A study with 1st-year undergraduates on a chemistry course in biotechnology self-assessing technical laboratory skills, supported by explicit performance standards, was conducted by Lau (2020). Two interventions, a self-assessment (SA) checklist and a learner-recorded video, examined how these impacted appraisal abilities. All the participants self-assessed titration competencies against a checklist, and about half were supported by video replay. Self-assessment with video showed a significant main effect, and these students were more targeted in their critique responses.

The effects of self-assessment and indirect teacher feedback on self-regulated learning (SRL) in the English as a Second Language context was investigated by Vasu et al. (2020). Three intact classes were randomly assigned to experimental and control groups, who completed the Self-Regulation Strategy Inventory Self-Report. Qualitative data were derived from the SRL microanalytic protocol. Both self-assessment and indirect teacher feedback helped learners become more self-regulated. However, self-assessment reduced maladaptive behaviors more than indirect teacher feedback. It was concluded that self-assessment is an effective instructional practice that promotes SRL in terms of goal setting, strategy planning, strategy use, attribution and adaptive behavior.

Discussion and conclusion

Discussion

Turning now to draw together the threads that have emerged from this brief survey, we must bear in mind that the papers selected in each of the three later categories (primary, secondary, higher) were merely a selection, and do not pretend to encompass all the factors that might be relevant. Nonetheless, we will find a number of commonalities. Looking first at the introduction section, for both peer assessment and self-assessment definitions were given and the underlying theory briefly addressed. The concept of reliability was addressed and it was noted that correlation with instructor scores was better referred to as "consistency". Some of the differences between face-to-face and digital peer and self-assessment were considered, with advantages and disadvantages found on both sides.

Considering the narrative and systematic reviews and meta-analyses, we see that overall peer assessment and self-assessment appear to be more or less equally effective. Both emphasize the positive effect of training. The peer assessment reviews emphasized psychological safety, value diversity, interdependence and generalizability, and the effect of duration of project. The self-assessment reviews emphasized the importance of co-designing criteria, self-efficacy, the association with self-regulation and the wide variety of subjects to which self-assessment was applied. In fact, however, all these factors could be applied equally to either peer assessment or self-assessment. If you wanted to do both, an issue here is which would you do first. Peer assessment, particularly with more than one assessor, is likely to give a much broader view of the value of your products, and may sensitize you to criteria which would benefit later self-assessment. On the other hand, self-assessment is less challenging, and may provide a less threatening introduction to some of the key concepts.

This commonality continues when we consider the primary (elementary) education sector, where we find self-efficacy reported on in both peer assessment and self-assessment. The important of confidence and pupils feeling enabled to apply themselves in

their own way cannot be over-estimated. There seems to be more emphasis on technology in peer assessment, with several mentions of web-based and sometimes virtual reality activity. In primary there is considerable mention of the effects of peer assessment on critical thinking, while in self-assessment there is considerable emphasis on the effect of rubrics. Again, with a larger sample of papers we would likely see more cross-over between peer and self-assessment.

Considering primary peer assessment only, we see mention of the importance of pupils becoming creative thinkers, effective communicators and collaborative team workers. Feedback is more effective if there is time to reflect and revise. Social skills interventions can raise self-esteem and improve academic achievement. Peer assessment has worked with concept cartoons and concept maps. Oral feedback seems effective than written feedback. Peer assessment can be used effectively with children with special educational needs. Females tend to show more consistency with teacher assessments than do males.

From a primary self-assessment viewpoint, a model essay coupled with criteria was effective, and self-assessment capability improved with increased age and with better literacy performance. A mentoring (training) program was very effective for low-socio-economic-status children. In a highly teacher-directed context, psychological safety was very important.

Turning now to secondary education, we find that for both peer assessment and self-assessment rubrics are very important, together again with self-efficacy. Application to e-portfolios was mentioned in both cases. Writing competence was also said to have improved under both interventions.

Under peer assessment, the effectiveness of reinforcing and suggestive feedback was mentioned more than once, and critical thinking also appeared again. Peer assessment in music and art were highlighted, emphasizing relevance to subjects other than core subjects. Virtual reality was used. Comments needed to be justified and reliability went up with the number of graders. Peer assessment led to lower anxiety.

Under self-assessment, self-regulation appeared again. Modeling, examples and practice featured, as did a few selected criteria rather than many. High correlation of self-assessment to subsequent formal examinations was mentioned. Novel means of self-assessment via visual rubrics and self-assessment diaries were reported.

Finally, we turn to higher education. For both peer assessment and self-assessment, video was frequently used to add value to the process. Both interventions also emphasized the use of explicit assessment criteria. Teaching English as a Foreign Language featured for both interventions, and work with pre-service teachers appeared twice under peer assessment.

For peer assessment, again practice and critical thinking were mentioned. Again, use in artistic subjects featured—one in dance choreography and one in musical theater. There was mention of training in co-defining criteria and giving feedback, the role of observation and practice, that general was better than specific feedback, and that feedback from multiple peers was more reliable than from a single peer. In terms of technology, PDAs and annotation of videos featured. Comparisons between peers were found effective in the absence of criteria, while grading with commenting was more effective than grading alone.

Self-assessment operated in counseling skills and engineering (very different subjects), and in the latter subject women were found to have lower self-efficacy (although that might be subject-specific). Self-regulated learning was mentioned frequently again. Self-assessment was as effective as teacher feedback but reduced maladaptive behavior more.

Many teachers in all sectors of education use both peer assessment and self-assessment. Returning to the interesting question posed earlier in this Discussion: in what order should they be used? My own opinion is that face-to-face peer assessment should be used before digital peer assessment wherever that is possible, that peer assessment should be used before self-assessment, and that self-assessment alone should be used before self-assessment with video. Of course, this is just an opinion. A research investigation which compared the effects of different orders of involvement in these interventions would be highly desirable (albeit large and expensive). Naturally, this would then need doing in each sector of education separately, and also in different subject areas – a massive undertaking.

Conclusion

Overall, then, peer assessment and self-assessment both appear equally effective. Both are used in a wide variety of subjects, including music, art, education, English as a Foreign Language, counseling and engineering. Many initiatives deployed technology, including PDAs and virtual reality. Two factors were emphasized most: (1) the need to co-design explicit criteria with students, and (2) the important role of self-efficacy in both interventions. Both were thought to lead to self-regulation of learning, although this was more prominent with self-assessment. Beyond this, there was much emphasis on the importance of training, which could include modeling or observation and should include practice. Rubrics were frequently mentioned (closely connected to co-designed criteria). Both methods could lead to improved critical thinking. The number of assessors was important, several being better than one (particularly in peer assessment). Video was often added to self-assessment in various ways to improve accuracy. Finally, psychological safety was important. Trust had to be developed between students and teachers and between students and students, and this is obviously linked to the issue of self-efficacy.

Although the literature is now quite extensive, neither peer assessment nor self-assessment are as widely used as one might expect, given that they have the advantage that they appear to transfer the burden of assessment at least partly to the student and thus lighten the load of the teacher. Some schools have a whole-school policy on peer learning, which may well include peer assessment and self-assessment, but these are in the minority. In the university sector, while peer assessment and self-assessment might feature in many universities in a few departments or subjects, but whole-university approaches are much less common. Now that we are more aware of the conditions necessary to make these interventions work, we are in a stronger position to increase their take-up.

Glossary

Classroom feedback practice How feedback is exercised in classroom contexts based on the beliefs teachers and students hold about feedback

Feedback agency A learner's adaptive or maladaptive agency in relation to internal feedback generated by the self and/or external feedback provided by others

Feedback dialog Internal or external feedback provided and generated through dialogic interactions

Responsive pedagogy The recursive dialog between a student's internal feedback and feedback provided by external agents (e.g., teachers, peers, parents, or digital resources)

Self-regulated learning How a learner metacognitively, motivationally, emotionally, and behaviorally regulates one's learning processes

Self-efficacy A learner's beliefs in one's capabilities to exercise influence and execute actions to attain desired goals

Introduction

This conceptual paper proposes a framework for classroom feedback practice as responsive pedagogy, based on key trends in the international research literature. Responsive pedagogy is defined as the recursive dialog between a student's internal feedback and feedback provided by external agents (e.g., teachers, peers, parents, or digital resources). Feedback is a powerful influencer of student learning when it clarifies understanding, bolsters motivation, and supports improvement (Ajjawi et al., 2022; Black and Wiliam, 1998a; Gamlem and Smith, 2013; Hattie and Timperley, 2007; Orsmond et al., 2005; Shute, 2008). Several studies have highlighted the importance of dialogic feedback for students' learning and achievement (e.g., Askew and Lodge, 2000; Carless, 2020; Gamlem and Smith, 2013). However, empirical studies have found an absence of dialogic feedback interactions in observed lessons (e.g., Gamlem and Smith, 2013). Classroom interactions are too complex for research to tell teachers what to do, but research can inform and support teachers' feedback practices. In addition, teachers exercise professional judgment in feedback interactions, which are realized through unplanned pedagogical moments of classroom interactions (Smith, 2015; Wyatt-Smith and Klenowski, 2013). When feedback is used in a formative process, students become more active and engaged in regulating their learning (Andrade, 2010; Brandmo et al., 2020; Gamlem et al., 2019; Vattøy and Gamlem, 2020).

Classroom feedback practices have resisted change due to a focus on one-way information delivery to students (Boud and Molloy, 2013; Gamlem, 2015a). A transmission model of feedback is argued for as questionable as it assumes a passive student role (Ajjawi et al., 2022; Gamlem and Smith, 2013; van der Kleij et al., 2019). Furthermore, feedback has often been interpreted by teachers and students as information provided by an agent—for example, a teacher, peer, or self—about aspects of performance or understanding (Hattie and Timperley, 2007). Since students need support and information on how to improve, this approach is insufficient for the implementation of powerful feedback processes (Andrade and Brookhart, 2020). Goals, dialogs, emotions, student agency, and opportunities to make sense of comments are essential in feedback practices (Harris et al., 2018; Panadero and Lipnevich, 2022; Winstone and Carless, 2020; Winstone et al., 2017). Responsive pedagogy emphasizes the importance of dialogic feedback interactions in classroom contexts, which ultimately open the door for more equitable feedback dialogs with students seeking feedback from and providing it to teachers (Smith et al., 2016; Vattøy and Smith, 2019).

Feedback in classrooms has often taken the form of written comments or grades on an assessment task; this is an approach which often focuses on justifying an assessed grade and controlling that the assignments are completed (Black and Wiliam, 1998a; Gamlem and Smith, 2013; Gamlem 2015a). One of the most significant limitations of this accountability model of feedback is that it does little in supporting the agency of students in improving their work (Askew and Lodge, 2000; Boud and Molloy, 2013). Research on responsive pedagogy has identified a hidden accountability system that impedes effective feedback dialogs due to a systemic focus on examinations and testing of students (Vattøy, 2020; Vattøy et al., 2020). Empirical studies have documented that teachers and student express different views as to the usefulness of feedback (Carless, 2006; Gamlem, 2015a). In many situations teachers' feedback in classrooms is neither recognized by students nor perceived as useful (Gamlem and Smith, 2013; van der Kleij and Adie, 2020; Vattøy et al., 2020). Indeed, much of the literature has documented students' barriers, discomfort, and irritation with feedback provided by a teacher (e.g., Winstone et al., 2017).

Conceptualized within a learning process, classroom feedback is not just a way of accounting for students' achievements—it is also integral to teaching and learning, where teachers and students have important roles to play (Andrade and Brookhart, 2020; Gamlem, 2015a; Gamlem and Smith, 2013; Henderson et al., 2019). The importance of students actively engaging with feedback processes has been emphasized in studies that have focused on how students perceive classroom feedback (Gamlem and Smith, 2013; Lui and Andrade, 2022; Winstone et al., 2017). In addition, Winstone et al. (2017, p. 17) argued for students' proactive receipt of feedback and emphasized "the fundamental contribution and responsibility of the learner." If feedback is not received by students, or not perceived as intended by the teacher or peer, it is unlikely that the feedback will achieve its intended effect of supporting student learning (Gamlem and Smith, 2013; Perrenoud, 1998; Sadler, 2010; van der Kleij and Adie, 2020). A study by van der Kleij and Adie (2020) provides evidence that feedback perceptions—and thus feedback effectiveness—are context-dependent, subject-dependent, and individual-dependent. In this view, the effectiveness of classroom feedback is dependent on whether students perceive it as effective. As stated by Gamlem (2015a), feedback processes might be hard to manage. The emerging concept of teacher feedback literacy has highlighted the teacher's role as a designer of classroom settings that promote students' feedback literacy (Carless and Winstone, 2020). Teacher feedback literacy consists of designing effective feedback processes, responding to the relational aspects of feedback and navigating tensions between the different functions of feedback. The development of student and teacher feedback literacy benefits from situations when teachers and students share goals, strategies, and responsibilities (Carless and Winstone, 2020). In contrast, a focus on feedback as "telling" might explain why students do not recognize all forms of feedback they are exposed to, such as peer feedback or oral feedback (Ajjawi et al., 2022; McLean et al., 2015; Sadler, 2010).

Classroom feedback informed by responsive pedagogy

Recently, there has been a call to embed assessment and feedback in the wider field of pedagogy (Black and Wiliam, 2018; Smith, 2015). This is a realization that learning-oriented assessment is not merely an ambitious goal but a profound shift in thinking and habits (Earl, 2013; Wiliam, 2020). Responsive pedagogy embeds classroom feedback in pedagogy and draws attention to the relevance of feedback dialogs in classroom settings (Smith, 2015; Smith et al., 2016; Gamlem et al., 2019; Vattøy and Gamlem, 2020). A dialogic model of feedback has been connected to a more active student role (van der Kleij et al., 2019). In responsive pedagogy, a key concern is activating students as agents in their learning processes through feedback dialogs (Smith et al., 2016; Vattøy and Gamlem, 2020).

A goal in responsive pedagogy is to capitalize on teacher-student interactions, emphasizing students' internal feedback dialog, to strengthen self-efficacy and self-regulated learning (Smith et al., 2016; Vattøy and Gamlem, 2020). This approach aligns with research by Nicol (2021), where "internal feedback" is argued for as an approach to extending the idea of student-centeredness in feedback. Nicol argues that a process of making inner comparisons is the underlying mechanism at play in all feedback processes (Ajjawi et al., 2022; Nicol, 2021). The interplay between internal and external feedback has highlighted the importance of students' metacognitive processes and self-monitoring for their self-regulated learning (Butler and Winne, 1995). The student's internal feedback is understood through the three phases of self-regulation: forethought, performance, and self-reflection (Zimmerman et al., 2017). These three phases can be exemplified by the fact that when a student is given an assignment, the student will begin an internal dialog with themselves about what the assignment is about and their competence in relation to goal. The student forms a pre-understanding of his or her personal knowledge needed to complete the assignment (forethought phase). Furthermore, the student will search for and decide what strategies are needed to achieve the learning objectives. In the performance phase the student actively monitors his or her learning processes. This is the student's internal dialog that the teacher, in his or her interaction with the student, tries to understand and respond to through a recurring feedback dialog that can support the student's learning. These dialogs can provide clarity and deeper understanding of the outcome of an assignment based on learning objectives and assessment criteria (self-reflection phase).

The recursive dialog between internal and external feedback highlights the importance of teacher scaffolding in students' self-regulation processes (Butler and Winne, 1995; Gamlem et al., 2019; Smith et al., 2016). Self-regulated learning has been defined as "an active, constructive process whereby students set goals for their learning and then attempt to monitor, regulate and control their cognition, motivation and behavior" (Pintrich, 2000, p. 453). The active self-monitoring process in responsive pedagogy is interconnected with external feedback from teachers, peers, or parents (Smith et al., 2016). The concept of feedback agency is relevant in this context, as students exercise adaptive or maladaptive feedback agency in feedback processes (Harris et al., 2018; Vattøy et al., 2020). The key concern for the teacher is to tap into the internal feedback dialog of the student in unplanned pedagogical

moments to scaffold the student's learning processes (Smith et al., 2016). In recent years, several researchers have pointed to the notion of feedback as the crucial interaction between teachers and students carried out for the purpose of fostering student learning (e.g., Gamlem and Smith, 2013; Hawe et al., 2008; Shute, 2008; Vattøy and Gamlem, 2020).

A framework for classroom feedback practice as responsive pedagogy

The proposed framework for classroom feedback practice as responsive pedagogy comprises six dimensions: goals, feedback strategy, feedback content, feedback dialog, self-efficacy, and emotions. The framework explains how classroom feedback functions as a guide for teachers' and students' feedback processes. Feedback agency is central for understanding how these six dimensions interact and influence one another. These dimensions are explained in detail below.

Goals

The connection between learning goals and self-regulated learning is central in responsive pedagogy (Gamlem et al., 2019; Gamlem and Munthe, 2014). Students exercise feedback agency by internalizing or rejecting external goals (Butler and Winne, 1995; Harris et al., 2018; Lui and Andrade, 2022). Goal orientation is linked to self-regulated learning as students set goals for their learning and aim to regulate their cognition, motivation, and behavior (Brandmo et al., 2020; Pintrich, 2000). Self-regulated learning can be described as the process where the learner activates and sustains their behaviors, cognition, motivation, and feelings toward the attainment of a learning goal (Schunk and Green, 2018).

External goal orientation is defined as "students' comprehension and activation or rejection of external learning goals set by the teacher" (Vattøy and Smith, 2019, p. 261). A study that examined dimensions of responsive pedagogy found that external goal orientation was the strongest predictor of students' perceptions of teachers' feedback practice (Vattøy and Smith, 2019). Students also felt more confident in their skills and were able to regulate when they knew the goals related to the teachers' feedback. However, classroom studies that have examined the role of feedback have indicated that teachers struggle to facilitate clear learning goals, which might impede students' own goal setting (e.g., Gamlem and Munthe, 2014; Vattøy and Gamlem, 2020). Attention to learning goals when engaging in learning activities and achievement tasks is important for the teacher and student (Brandmo et al., 2020; Gamlem and Munthe, 2014; Lui and Andrade, 2022). Without clear learning intentions and goals, students may have problems knowing in which direction to move (Hattie and Timperley, 2007; Sadler, 1998, 2010). Furthermore, feedback should be linked with learning goals (Gamlem and Smith, 2013). Feedback dialogs are important for students to identify criteria and goals (Sadler, 2010). Feedback that supports students' self-regulated learning can get students to set their own goals related to the task they are given, to plan how they can solve the task, and to check whether they are on the right track (Andrade, 2010; Andrade and Brookhart, 2020; Sadler, 2010). This aligns with self-regulated learning, which is defined in responsive pedagogy by inspiration from the work of Pintrich and Zuscho (2002): an active constructive process in which students set goals for their learning and monitor, regulate, and control their cognition, motivation, emotions, and behavior, guided and limited by their goals and contextual characteristics of the environment.

Feedback strategy

The development of feedback strategies is a key concern in responsive pedagogy, with the emphasis on how students gain strategic knowledge and skills in seeking feedback from teachers and providing feedback to their peers (Smith et al., 2016; Vattøy and Smith, 2019). Feedback strategies can vary in timing (when given, how often), amount (how many points made, how much about each point), mode (oral, written, visual/demonstration), and audience (individual, group, class, teacher, student), (Brookhart, 2008; Panadero and Lipnevich, 2022; Gamlem and Smith, 2013). Students choose strategies when working independently and engaging in peer feedback dialogs. Feedback as a process in which students and teachers make sense of information about their performance and use it to enhance the quality of their work or learning strategies is key (Boud and Molloy, 2013; Carless, 2020).

Working with feedback does not come naturally to all students, and researchers have stated that teachers should teach students how to use received feedback and how to seek feedback to improve their work and increase performance (Ajjawi et al., 2022; Andrade, 2010; Gamlem and Munthe, 2014; Henderson et al., 2019; Sadler, 2010). Students are often unused to or prevented by constraints of the classroom context from seeking feedback, or when they do, they may be unable to judge the relevance of the comments (Gamlem and Smith, 2013; Winstone et al., 2017). Students need to be trained in how to interpret feedback, how to make connections between the feedback and the characteristics of the work they produce, and how they can improve their work in the future by seeking and using feedback (Black and Wiliam, 2009; Henderson et al., 2019; Sadler, 2010).

Feedback content

Feedback content is essential for students' understanding of performance and how to improve (Black and Wiliam, 1998a; Panadero and Lipnevich, 2022; Perrenoud, 1998; Shute, 2008). Students who are not provided with strategic feedback or with clear explanations of their specific errors or what made their work superb might have difficulties understanding why they are performing poorly or excellently and what they need to do to improve (Andrade and Brookhart, 2020; Black and Wiliam, 1998b).

Feedback content varies in focus (task, process, self-regulation, self), comparison (criterion-referenced, norm-referenced, self-referenced), function (description, judgment), valence (positive, negative), clarity (clear/unclear to a recipient), specificity (specific, general), and tone (implication, climate), (Brookhart, 2008; Gamlem and Smith, 2013; Hattie and Timperley, 2007; Panadero and Lipnevich, 2022).

However, the effectiveness of feedback content is dependent on both teachers and students. Empirical research has documented teachers' difficulties enhancing students' deeper understanding of content in feedback interactions (e.g., Vattøy and Gamlem, 2020). Feedback quality and feedback quantity have been identified as two important predictors of students' use of feedback (Vattøy et al., 2020). Henderson et al. (2019) emphasized the importance of both teachers and students understanding that feedback is a process, and comments given by a teacher are only one possible part of the process. Critically, students need to be able to make sense of feedback and then act upon it (Carless and Boud, 2018; Lui and Andrade, 2022; Sadler, 2010). As explained by Sadler (2010), feedback as the act of "telling" is not effective in facilitating student learning because the connection between feedback, students' work, and future learning relies on clear and unambiguous interpretations of that feedback, and often the key messages remain invisible to students. An implication is that classroom feedback needs to be constructed so that it can be easily understood and acted upon (Ajjawi et al., 2022; Gamlem and Smith, 2013; Henderson et al., 2019; Winstone et al., 2017). The focus has thus shifted from the teacher to the teacher and student(s) working in partnership (Ajjawi et al., 2022; Carless, 2020; Hawe et al., 2008).

Feedback dialog

The emphasis on feedback dialogs is important for students' active participation in giving, seeking, and receiving feedback to promote learning. The backdrop for the development of feedback dialogs in responsive pedagogy has sociocultural roots in the notion of a Vygotskyan dialog between internal and external feedback (Gamlem, 2015b; Smith, 2015; Vygotsky, 1978). Vygotsky's belief that language is fundamental to the process of learning and dependent upon the complex interplay of thought and language in shaping meaning is at the heart of how classroom talk and feedback promote learning, as conceptualized in responsive pedagogy (Smith et al., 2016; Vygotsky, 1962). Central to Vygotsky's sociocultural theory of learning is the idea that conceptual knowledge first appears between people on an interpsychological level and then inside the learner on an intrapsychological level (Vygotsky, 1978). The notion of a teacher assisting student performance in the zone of proximal development also suggests that teachers can guide discourse on the interpsychological level to support student learning (Gamlem, 2015b; Mercer and Littleton, 2007). This recognizes the importance of teacher-student discourse in the classroom, which may be considered a form of scaffolding, although the latter was originally conceived in the context of tutoring a single individual in problem-solving (Wood et al., 1976). In responsive pedagogy, teachers tap into and capitalize on students' internal feedback dialogs about emotions, self-efficacy, and self-regulation processes via the external feedback that occurs recursively (Gamlem et al., 2019; Vattøy, 2020; Vattøy and Gamlem, 2020). Carless (2020) emphasizes the importance of partnerships between teachers and students in feedback dialogs, where teachers have as much to learn as students. For example, teacher-student feedback dialogs give a teacher a chance to see whether feedback content was appropriate and whether his or her teaching prepared the students adequately for the learning goals.

Self-efficacy

Self-efficacy is defined as a learner's beliefs in his or her capabilities to exercise, influence, and execute actions to attain desired goals (Bandura, 1977; Zimmerman et al., 2017). This concerns the learner's ability to organize and carry out actions required to achieve a given result (Bandura, 1997; Lui and Andrade, 2022). Self-efficacy as a concept originates from Bandura's (1977) social-cognitive theory, involving the individual's development and exercise of self-control over desired outcome. Zimmerman (2000, p. 86) stated that "self-efficacy beliefs have shown convergent validity in influencing such key indices of academic motivation as choice of activities, persistence, level of effort, and emotional reactions." In classroom contexts, students' beliefs about their efficacy to manage academic tasks can also influence them emotionally by decreasing anxiety, depression, and stress (Bandura, 1997; Gamlem et al., 2019; Pekrun et al., 2002). An intervention study focused on responsive pedagogy found short-term effects on students' self-efficacy, motivation, and self-regulation (Gamlem et al., 2019). Such results seem to indicate the relevance of training teachers specifically in terms of facilitating feedback dialogs that promote students' beliefs in their capabilities. Yet, unrealistic expectations about grades and a summative accountability system have been identified as negative factors working against teachers' work in supporting students' self-efficacy (Vattøy, 2020).

Emotions

Emotions facilitate or impede students' self-regulation of learning (Ajjawi et al., 2022; Pekrun et al., 2002). Winstone and Carless (2020, p. 150) state that "the relationship between emotions and feedback is complex," since praise can elicit positive emotions, and at the same time it can undermine the motivation to invest future effort. Pekrun (2006) found that emotions differ not only according to valence (positive/negative) but also students' activation potential. Students activate emotions by initiating action and effort or deactivate them by inhibiting action and effort. Positive activating emotions such as enjoyment of learning may generally enhance academic motivation, whereas negative emotions may be detrimental (Harley et al., 2019; Panadero and Lipnevich, 2022;

Pekrun et al., 2002). Both negative (e.g., shame) and positive (e.g., relief) emotions can lead to outcomes that are either aligned or misaligned with students' academic goals, depending on how they deal with these emotions (Ajjawi et al., 2022; Harley et al., 2019). Emotional aspects (e.g., enjoyment or anxiety) have been found to be significantly associated with other dimensions of responsive pedagogy, such as self-efficacy and self-regulation (Gamlem et al., 2019). Enjoyment has also been found to significantly predict students' external goal orientation, self-regulation, and perceived usefulness of teachers' feedback practice (Vattøy and Smith, 2019). Emotions and feedback are connected, as students who invest a high degree of energy and effort but receive disapproval from their teacher might lose motivation (Gamlem and Smith, 2013; Panadero and Lipnevich, 2022). Emotional aspects such as mistrust and negativity have been found to cause maladaptive feedback agency in students (Gamlem and Smith, 2013; Vattøy et al., 2020). Emotions might become more relevant and influence how feedback is interpreted and acted on, due to students' active and interpretive stance (Ajjawi et al., 2022).

A model of effective classroom feedback informed by responsive pedagogy

Fig. 1 visualizes the reciprocal relationship between the dimensions that influence effective classroom feedback informed by responsive pedagogy: goals, strategy, feedback content, feedback dialog, self-efficacy, and emotions. The arrows visualize how each dimension affects and is affected by other dimensions. Feedback agency is at the core of understanding the model, as students exercise adaptive or maladaptive influence on teaching and learning processes.

Effective classroom feedback practice as responsive pedagogy is dialogic. The student starts with, for example, goals, selects strategies, and monitors his or her processes during the provision and generation of feedback content. Students and teachers engage in recursive feedback dialogs in which internal feedback is externalized and becomes clearer to the student. The clarity of the preceding phases causes the student to have increased self-efficacy, supported by the teacher. A positive learning experience and feedback interaction causes positive emotions and attainment. However, these processes might transpire differently (e.g., emotional reactions as points of departure).

Effective classroom feedback involves continually challenging and improving one's practice (Gamlem, 2015a; Henderson et al., 2019; Vattøy et al., 2020). This requires a degree of self-reflection on the part of teachers and students, along with an inquiry mindset (Smith, 2015). The proposed model of effective classroom feedback as responsive pedagogy might increase teachers' valuation of students' experiences of feedback. Although classroom interactions are inherently complex and sometimes bewildering, the model of effective classroom practice might support teachers' professional judgment processes. The model also contributes to understanding the dimensions that students are affected by in their feedback interactions, which consequently affect their learning. Understanding students' encounters with classroom feedback might contribute to understanding students' learning trajectories and support teachers in providing support in feedback processes. Recognizing students' feedback agency implies understanding that students exercise adaptive or maladaptive influences in feedback dialogs (Harris et al., 2018; Vattøy et al., 2020). Thus, a key concern in classroom feedback practice is supporting students' feedback agency processes (as visualized in the six dimensions) to strengthen their learning.

Fig. 1 A model of classroom feedback agency processes informed by responsive pedagogy.

Conclusion

This paper proposed a framework for classroom feedback practice as responsive pedagogy comprising six interacting dimensions: goals, strategy, feedback content, feedback dialog, self-efficacy, and emotions. Furthermore, a model was introduced to visualize how the dimensions interact and influence one another. A fundamental aspect of the model is how students' feedback agency processes are acknowledged and actively worked with in classroom feedback dialogs. A key concern is how teachers support students in setting goals and selecting strategies and how they monitor their learning processes during the work with feedback content. Teachers and students engage in recursive feedback dialogs that activate internal feedback through external dialogs. Teachers support students' self-efficacy and beliefs in their capabilities, recognizing and caring for students' emotions in feedback processes. Since students exercise feedback agency, the interacting dimensions might alter the way the dimensions affect feedback agency processes. We argue that responsive pedagogy seems to be an approach to supporting students' internal feedback processes via teacher-student feedback dialogs in classroom practice.

Glossary

Dynamic assessment A form of diagnostic assessment which looks at what progress a learner can make when offered adult support in a one-to-one situation

Educational assessment An approach which focuses on an individual achievement relative to him or herself rather than to others, places little emphasis on standardization and seeks to help the individual progress. It is contrasted with psychometric testing

Formative assessment Assessment used to inform teaching and learning so that further learning takes place

International Baccalaureate (IB) A high status international diploma offered in three languages around the world

Performance assessment Judging what students can do in terms of the actual tasks and end performances that are the goals of instruction (Used interchangeably with “authentic assessments” and “direct assessments”).

Psychometric testing Assessment which focuses on standardization of tasks and scoring, on norms and distributions

Realistic simulation Seeking to represent the intended real-world performance, for example, a flight simulator for trainee pilots

Social constructivist Cognitive and sociocultural theories of learning which emphasize the importance of students actively making meaning in their learning and the role of the social context

Summative assessment Assessment which “sums up” where learners have got to in their learning

Systemically valid testing Assessment which leads to curriculum and instructional changes that foster the cognitive skills that the test measures

Introduction

Alternative assessment is an elastic term which stretches from doing the same thing in a different format to describing radically different ways of approaching assessment. These are alternatives to conventional “pencil-and-paper” standardized tests and examinations. Alternative assessments include performance, authentic, formative, and diagnostic assessments. These terms overlap and

reflect alternative approaches to both learning and assessment. A function of this contribution is to clarify, and question, the way the term alternative assessment is used.

Alternative assessments can be classified into three levels: alternative formats of assessment, alternative forms of assessment; and alternative uses of assessment. While there are considerable overlaps among these, the distinctions may be useful in discussing the extent of the differences from conventional assessment. Examples are considered from each of these levels.

Level 1: Alternative formats

The alternative label is usually applied at this level to new or different delivery of an assessment—for example, transferring a pencil-and-paper test to a computer screen. The test content and demands remain much the same while the means of delivery changes. It may be the case that as the computer testing becomes more sophisticated, it begins to make new demands and might move to the next level—for example, using multimodal stimulus materials or forms of computer-adaptive testing.

Where a particular form of assessment is dominant—for example, multiple-choice testing in the USA—then, more open-ended tests requiring constructed answers have also been claimed to be alternative, in the sense that they are different. It may be that, once again, little else changes in the test demands and accompanying pedagogy. We would challenge whether this kind of claim should automatically be called alternative, since it is essentially business-as-usual with varied assessment formats. Little changes in what is assessed and in classroom teaching and learning.

Continuous Assessment by teachers, for example the Grade Point Average (GPA) in the North American education system, may fall into this category. These assessments are less standardized than external tests but often may cover the same curriculum as the end of unit/course test. However, where the classroom teaching and learning is more imaginative and goes beyond this narrowed curriculum and includes, for example, projects, debates and group work it may best be considered as Level 2.

Level 2: Alternative forms of assessment

Hanson has highlighted the “fabricating quality of tests” in which “the likelihood that someone will be able to do something, as determined by the tests, becomes more important than one’s actually doing it” (1994: 288). At this level, changes in assessment are underpinned by the intention to provide a different approach to assessment which focuses on performance of the skills themselves. This can be illustrated through developments in performance and authentic assessments—terms which are used interchangeably here. These assessments emphasize direct, or as direct as possible, demonstration of the skill being assessed and minimize the use of tests as a proxy for actual performance. This is a long-standing tradition in many occupational areas, and there have been moves to apply this within more general education. At a conceptual level these approaches to assessment have been encouraged by a shift toward more constructivist theories of learning. These encourage a more holistic and “sense-making” approach to learning and its assessment in contrast to the “knowledge-in-bits” of most multiple-choice tests which behaviorist views of learning have encouraged.

Along with these conceptual shifts in approaches to learning, the drive to develop alternative models of assessment has received support from the fact that traditional types of test, for example, multiple-choice standardized tests in the US and formal written examinations in the UK, have had unintended and negative effects on teaching and on the curriculum. This is particularly the case where test results play a central role in educational accountability systems, with test results used to evaluate school performance by local authorities and government. The “high stakes” use of tests in countries such as the United States, England and Chile have narrowed the curriculum as teachers “teach the test”. “Under intense political pressure, test scores are likely to go up without a corresponding improvement in student learning. In fact, distortions in what and how students are taught may actually decrease students’ conceptual understanding” (Shepard, 2000: 13).

Performance assessment

Shepard and Bleim (1995) have argued for the equivalence of some of the key terms: “We use the terms performance assessments, authentic assessments and direct assessments interchangeably, the idea being to judge what students can do in terms of the actual tasks and end performances that are the goals of instruction” (p. 25). While this equivalence may not satisfy all, it provides us with a broad base from which to work. The spirit of this approach is to offer assessments which relate as closely as possible to the real-life knowledge and skills required. How close this match is may depend on the context. The philosophy behind this approach is straightforward: to be assessed as having a skill or competency we need to demonstrate it.

Two well-established forms of performance assessment, both of which have their roots in occupational and vocational training, illustrate this emphasis on practical demonstrations of competence. With pencil-and-paper testing so dominant in the education sector, these serve as a reminder of other models of assessment which have a long-established pedigree.

Competency assessment in the workplace

The most direct correspondence between learning a skill is competency assessment in the workplace. We would expect our trainee doctors, plumbers, and pilots to have demonstrated competency in real-life situations. It is the same with musicians and drama

students; they will be assessed on the basis of actual performances. A key feature of these assessments is that they rely on expert human judgment. Competency assessment was embodied in the medieval guild system, in which persons would be apprenticed and would then, after learning their trade for a number of years, demonstrate the skills in their craft through their products. It was the quality of these products that determined their admittance to the guild. This is a distinctly different form of assessment from psychometric approaches which seek to minimize individual judgment and in which competency is often reduced to achieving the cut-score on multiple-choice tests.

Realistic simulation

This approach also seeks to align the assessment closely with the intended real-world performance, but may take place in a context, for example in a college, which relies on simulation. For example, medical training may involve direct simulation, using actors who mimic patients' symptoms. Similarly, trainee pilots will use flight simulators and trainee mechanics work on workshop engines. Another form of realistic simulation may be working under highly controlled and supervised conditions such as special catering events for trainee chefs, or conducting scientific experiments in school science laboratories. We consider these alternative assessments because they represent a model of learning-by-doing which differs from the dominant educational model in which tests become a proxy for the required skills and practical knowledge.

While we categorized early computer-based testing as little more than changing the format of the tests (paper to screen), many of the more sophisticated applications are able to offer realistic simulations through multimedia stimulus materials. We also recognize that adaptive testing, which responds to the student's choices and decisions, offers an alternative when, for example, it works to capture the student's own understanding of a problem.

Alternative forms of classroom assessment

The classroom rarely offers such clear-cut alternative assessment practices. There are, however, opportunities to move away from the dominant testing model and in doing so offer a richer curriculum and more in-depth learning. Some of these may be loosely described as performance assessments since they focus on what learners can demonstrate in less constrained settings than conventional standardized tests. These are often summative in purpose, though they contain many opportunities for formative assessment (see below).

Extended assignments/projects

In standardized tests, even the inclusion of constructed (open-ended) answers offer the candidates little room to express their own understandings since they generally require convergent answers which are anticipated by the mark scheme. An alternative approach, which sits well with constructivist principles, is to provide the learner with opportunities to create a substantial piece of work in which they have choice over what they do. At classroom level, this may be projects which explore local issues—for example, history projects, or which feature the students' own designs in technology. This may also incorporate group activities which would encourage the collaborative aspects of learning.

A useful example of how individual projects can be managed is provided by the extended essay in the International Baccalaureate (IB)—a high-status international diploma for 16–18-year-olds offered in three languages around the world. The extended essay is an independent, self-directed piece of research, culminating in a 4000-word paper which contributes to the diploma. It involves an in-depth study of a topic of interest within a chosen subject, with the emphasis placed on the research process: formulating an appropriate research question; engaging in a personal exploration of the topic; communicating ideas; and developing an argument. The assessment of this process is by the students' own teachers, who have received professional development in marking the essays. There is considerable external confidence in the dependability of IB assessments, especially among universities for whom the extended essay is a good preparation for similar work at degree level.

Assessment by teachers for external purposes

Teachers regularly assess their students' classroom learning for both formative and summative purposes. The interest here is in those assessments which are used as part of external certification or for high-stakes selection purposes. Such assessments can be considered as alternative assessments when they both replace conventional standardized testing and encourage a broader approach to teaching and learning.

Much classroom assessment may not meet these requirements since it mimics standardized tests and is little more than frequent summative testing which is used for reporting or management purposes rather than as formatively contributing to students' further learning. Continuous assessments such as the grade point average (GPA) in US classrooms can be seen as a means of keeping learning and effort on track—a form of classroom control, rather than encouraging the principles of educational assessment.

A useful model for this broader approach to teaching and learning which encourages deeper understanding is [Frederiksen and Collins' \(1989\)](#) principles of systemically valid testing. At the heart of this approach is the principle that:

A systemically valid test is one that induces in the education system curricular and instructional changes that foster the development of the cognitive skills that the test is designed to measure. Evidence for systemic validity would be an improvement in those skills after the test has been in place within the education system for a period of time (p. 27).

They proposed standards for assessment which included:

Directness. This involves assessing the cognitive skill of interest—the emphasis being on the authenticity of the extended tasks. They call for sets of tasks which are ecologically valid, which are representative of the way knowledge and skills are used in real-world contexts, and for which the primary traits have been identified.

Scope. This considers the range of skills needed to do well in the tasks.

Reliability. This seeks effective ways of assessing which, at the same time, fosters learning.

Transparency. This is the concern that those being assessed are clear about how they are being judged. This should enable learners to “assess themselves and others with almost the same reliability as the actual test evaluators achieve” (p. 30).

This theoretical framework can be applied to a variety of alternative assessments such as assessment by teachers which contribute to credentials as well as extended assignments and portfolio-based assessment.

An example of systemically valid assessment by teachers is that found in Queensland, Australia, which abolished examinations over 30 years ago and replaced them with criteria-based subject-achievement assessments by teachers. This offers an alternative to selection examinations and encouraging a richer curriculum in which teachers and students are actively involved in the assessments. The system involves extensive moderation by over 400 district review panels, composed mainly of teachers. These panels review samples of work across subjects and schools and provide advice to schools. The process is seen as an effective form of professional development in assessment. However, increased accountability pressures within the Australian system have recently obliged Queensland to introduce some external testing in addition to the Queensland Core Skills Test (cognitive skills based on the common curriculum elements) which is taken by 17-year-olds wishing to enter university.

Portfolio assessment

At one level, portfolios may be regarded simply as collections of pieces of student work which are kept as a record. However, these collections can also be used as a basis for summative assessment, and so portfolios are often described as a method of assessment.

A portfolio used for assessment and learning purposes involves documentation of achievements, self-evaluation, process artifacts, and analyses of learning experiences. It is, therefore, significantly more than a collection of assignments (Klenowski, 2000: 219).

Using collections of student work for assessment allows a wide range of approaches to marking—from traditional marks and grades assigned by teachers, through detailed written comments by teachers (with no grades), teacher–student discussion, and negotiation of the assessment, to student self-evaluation. As with other forms of alternative assessment, the proponents of portfolio assessment present a rationale based on the enhancement of learning. First, assessment that celebrates achievement on a self-referenced or criterion-referenced basis builds students’ confidence and ultimately enhances their performance. These can be contrasted with the situation in which assessment draws attention to failure through the use of grades and marks, particularly when norm-referenced. Second, learning is enhanced if students understand clearly what they are trying to achieve and are provided with personal and substantive feedback in trying to reach their target. Third, collecting, sorting, and annotating evidence to demonstrate achievement in the form of a portfolio of work is a valuable aid in developing the skills of self-evaluation, as well as for communicating standards in a relatively unambiguous and accessible way.

Advocates see portfolio assessment as the embodiment of good social constructivist principles. While the validity of using these for summative purposes at a local level is strong, there have been far more challenges when portfolios have been used in relation to wide-scale accountability testing. Portfolio experiments in the USA, in the states of Vermont and Kentucky, led them to be incorporated into accountability measures, which then raised questions of reliability. For high-stakes purposes, portfolio assessments remain vulnerable to reliability problems relating to sampling, standardization, and scoring. In high-stakes assessment contexts, this will often leave them exposed to criticisms of bias and unreliability, particularly where it is the student’s own teacher who is making the assessment.

Theoretical underpinnings

The philosophy behind these alternative approaches distinguishes educational assessment from psychometric assessment. For present purposes, the key issues are that, in the psychometric model, the focus on reliability requires the standardization of administration and tasks as well as of scoring. The preoccupation of psychometrics with norms and norm-referenced testing stemmed from tests focused on aptitude, selection, and prediction. An individual’s performance was reported in relation to that of his/her peers, so that performance was seen in relative, rather than in absolute, terms. A recent debate (William and Baird, 2017) has questioned in what way psychometric approaches actually contribute to learning.

Alternative assessments can be seen as theoretically grounded in those learning theories which emphasize the importance of individuals constructing meaning for themselves within a social context and the importance of broader-based assessment.

Gipps (2011), for example, has argued that educational, as opposed to psychometric, assessment deals with the individual’s achievement relative to him or herself rather than to others; takes place in relatively uncontrolled conditions and so does not produce well-behaved data; looks for best—rather than typical—performances; is most effective when rules and regulations characteristic of standardized testing are relaxed; and embodies a constructive outlook on assessment, where the aim is to help rather than sentence the individual.

Shepard (2000) developed a conceptual framework for this understanding of assessment based on social constructivist theories of learning. She summarizes this view of learning in the following principles: (1) intellectual abilities are socially and culturally

developed; (2) learners construct knowledge and understandings within a social context; (3) new learning is shaped by prior knowledge and cultural perspectives; (4) intelligent thought involves metacognition or self-monitoring of learning and thinking; (5) deep understanding is principled and supports transfer; and (6) cognitive performance depends on dispositions and personal identity.

Summary

This section has reviewed examples of alternative assessments which seek to directly measure the desired skills and competencies rather than through the proxy of written tests. This is an approach historically grounded in occupational and vocational approaches to learning represented by the guild system. In educational settings, alternative approaches to assessment are based on different models of learning. Social constructivist approaches encourage students to make meaning and to understand the principles behind what they are doing. This leads to forms of assessment such as portfolios and extended project work. Classroom assessment by teachers will need to be interrogated to see if it is offering such opportunities.

Level 3: Alternative uses of assessment

The assessments considered so far have been primarily used for summative purposes, summing up where students have got in their learning. This section considers an alternative uses of assessment: the formative and the diagnostic. Formative assessment serves different purposes since its main intention is to assist the learning process rather than to measure what has been learned. Diagnostic assessment can be seen as a subset of this in seeking to find out what is known in order to help with further learning. There are considerable overlaps with the previous level: summative assessments can be used formatively if the results are used to guide further learning; performance and educational assessments will often involve the kind of self-regulation and feedback which characterize formative assessment.

What is the purpose of formative assessment?

The intention of formative assessment is to directly inform learning and teaching processes so that further learning takes place. This can be contrasted with summative assessment, in which the intention is to provide a summing up of where learners have got to in their learning. At the heart of formative assessment is the assumption that assessment, broadly understood as information gathering, can help identify what learners know, so that further teaching can build on this. It also assumes that learners will play an active part in the process and will increasingly be able to monitor and regulate their own learning. A key mechanism in this process is feedback, since this can help the learner bridge the gap between current and desired performance. My preference is to call this approach *assessment for learning* as this makes the intention clear. A useful definition is:

The process of seeking and interpreting evidence for use by learners and their teachers, to identify where the learners are in their learning, where they need to go to and how best to get there.

Assessment Reform Group (2002: 2–3).

This is essentially about day-to-day classroom assessment and depends on the quality of classroom interactions. It supports a pedagogy in which teachers seek to negotiate, and make explicit, learning intentions and success criteria (“where they need to go to”). It also involves finding out where learners are in their learning. This may be by diagnostic assessment—for example, miscue analysis in reading or investigating errors on tests. On a day-to-day basis, it occurs through classroom interaction—for example, questioning and dialog.

One practice which illustrates how assessment for learning can modify approaches to teaching and learning is that of “wait-time”. When teachers ask questions, they expect an almost immediate reply, the research suggests less than a second’s wait (Rowe, 1987). If effective learning is about the student-constructing meaning, what chance is there for this when an immediate answer is expected? Also, what kind of question only takes a second to process before answering? Wait-time, therefore, encourages the teacher to ask richer questions and allow students more time to process the answers (and there maybe more than one correct answer). This approach also encourages students to discuss briefly the answer with each other before the teacher asks for responses. This may also lead to following up on unexpected or incorrect answers since these misconceptions may help in understanding where learners are in their learning.

Wait-time is just one small example of how formative assessment may change the quality of classroom interaction. This is no longer the teacher using surface-level questions to check quickly whether students know the correct answers, it involves a more deliberate attempt to gauge their understanding.

Feedback

One of the key components of assessment for learning is feedback. Its role is to help move learners from where they are toward the desired standard—the “and how to get there” of the definition. What is known about feedback is that it does not always work as intended. In their meta-analysis of research on feedback, the psychologists Kluger and DeNisi (1996: 275–277) concluded that:

In over one third of cases Feedback Interventions reduced performance ... we believe that researchers and practitioners alike confuse their feelings that feedback is desirable with the question of whether Feedback Intervention benefits performance.

Whether feedback has positive learning effects depends on many interacting factors: motivation, the complexity of the task, the expertise of the learner, and the level and quality of the feedback. This makes it highly situational: the same feedback given to two learners could have opposite effects. Simply telling novice learners that they are wrong may set back learning, telling engaged experts the same may be enough to get them to increase their efforts and change their strategy.

Assessment for learning encourages feedback which focuses on the task rather than on the learner, and which has the goal of learners who become increasingly self-regulating. This involves being sufficiently aware of the desired standard that they can begin to give themselves, and their peers, feedback. This leads to alternative thinking about classroom practices, for example, questioning whether praise is an effective form of feedback (how does praise provide information to close the gap in learning?). It may also question routine marking and grading practices. For example, if the feedback to a piece of work is a mark (7/10) how does that provide information to move learning forward? Most teachers may put a comment alongside this—but research suggests that this is largely ignored, it is the mark that counts.

This leads to classroom practice with an emphasis on developing self-regulated learners who receive and use informative feedback. It leads to less emphasis on marks and grades, and more encouragement for comment-only marking.

The claim here is that formative assessment represents an alternative purpose for assessment: to contribute directly to the learning process. In terms of the approach to learning, it overlaps with the social constructivist views that we considered in the previous section and aligns well with approaches such as performance assessment and portfolios.

Diagnostic assessment

A further example of different purposes of assessment is its use for diagnosis. Genuine diagnostic testing can be seen as a subset of formative assessment (where the learners are in their learning). We distinguish this from diagnostic testing which is used for managerial purposes—for example, to allocate students to groups. Diagnostic testing can involve informal analysis—for example, of a pupil's reading skills and limitations—or the use of test results to identify what has not been understood. This test-and-remediate approach would often be called formative assessment in the US. In this, the formative element is in the remediation work following a test, occupying, for example, 1 week in a 6-week module. This approach to formative assessment differs from assessment for learning, which treats it as a continuous everyday classroom practice.

Dynamic assessment

An alternative approach to diagnostic assessment is provided by dynamic assessment. This has drawn on the sociocultural theories of Vygotsky (1978), who pointed to the importance of tools and aids in learning. What this diagnostic approach seeks to find out is what progress a learner can make when offered adult support in a one-to-one situation. It is therefore not so much what learners know, but how effectively they learn when assisted. In the traditional examination and test, the student is denied the use of external tools. As Lunt (1994) explains:

Dynamic assessment procedures ... involve a dynamic interactional exploration of a learner's learning and thinking process and aim to investigate a learner's strategies for learning and ways in which these may be extended or enhanced. Since it offers individuals an opportunity to learn, dynamic assessment has the potential to show important information about individual strategies and processes of learning and, therefore, to offer potentially useful suggestions about teaching (p. 152).

This approach—like formative assessment and educational assessment—represents a challenge to approaches to assessment found in the psychometric tradition. They are alternative not because they do the same thing differently but because they attempt to achieve something different. This difference is rooted in current understandings of how we learn and in a search for ways of aligning assessment with approaches to teaching and learning which emphasize the importance of using assessment to support good-quality learning. This requires a different relationship between assessor and learner, with learners playing an active part in their learning.

Summary

Alternative Assessment is an umbrella term which shelters a range of approaches to assessment which are outside the conventional formats of standardized tests. These have been grouped into three broad, and overlapping, categories which progressively indicate their distance from the typical psychometric model of test development. The first level involves alternative *formats*, in which test content is presented in alternative ways, for example by computer rather than on paper. The second level sees a move toward different assessment tasks or different ways of presenting evidence. Performance assessments involving demonstration of a skill

either directly (e.g., musical performance) or through simulation (e.g., pilot training) would represent this level. Alternative methods of assessing students' work through portfolios, extended essays or coursework are also part of this level. The third level involves alternative *purposes* for the assessments. While conventional tests are typically used for summative purposes, "summing up" where a student is at that moment, the purpose of formative assessment ("assessment for learning") is to feed directly, and more informally, into the learning process.

This three-level classification is intended to bring into clearer focus how assessments can be considered as "alternative".

Introduction – unraveling assessment as a phenomenon in education

Assessment is an inherent component of education. Ever since the dawn of educational activities, educators – and various stakeholders – have taken an interest in knowing whether students have actually learnt what they were supposed to have learnt (Broadfoot, 2007; Wiliam, 2010; Stobart, 2008). Some historical examples of education assessment practices are the Chinese civil servant examination instituted during the Qin Dynasty around 200 BC (Wang, 2013) and Roman students' cramming for the Law of the Twelve Tables from 450 BC in the Late Roman Republic (Cornell, 2012).

But assessment in education also has a long history of teachers and schools being assessed and held to account for their performance (Dorn and Ydesen, 2014). Over the last 60 years we have seen a move from indicators of input (curriculum) to indicators of output (achievement) and various versions of standalone schools, directly responsible for their own progress. This development is reflected in a shift in emphasis from streaming of students according to assessment of their abilities to the assessment of schools based on student and teacher data. In our own time, we have witnessed the global dissemination of an assessment agenda which places students' learning outcomes and educational standards at the forefront of policymakers' agendas (Hill and Kumar, 2009; Smith, 2016).

To the extent that we can discern future trajectories, we begin to see new forms of educational assessment taking shape, where real-time monitoring and artificial intelligence induced recommendations based on cross-references of performance scores and data about social background and biological capacities in individuals and cohorts are gaining ground (Williamson, 2018). In this sense, it is possible to speak of a development in educational assessment from the measurement of past progress (diagnostic assessment) into governing in relation to future projections of progress (prognostic assessment).¹

The history of educational assessment is however highly irregular (McArthur, 1987). This irregularity arises because assessment is not an unequivocal phenomenon. While educational assessment may be broadly defined as the judgment of performance, it has multiple inseparable and closely interwoven layers arising in relation to different stakeholders, instruments and purposes (Richardson, 2022; Stobart, 2008; Madaus et al., 2009). For instance, assessment may be used as a pedagogical, evaluation or governance tool, namely for the implementation or monitoring of policy and/or a device of accountability (Newton, 2007). While these uses are not necessarily mutually exclusive, they do add to the complexity surrounding educational assessment where various agendas, priorities, and ideals crisscross any development and enactment of educational assessment policies and practices.

In a broader sense, it can be argued that all societies to a certain extent are dependent on some form of assessment system to establish criteria of human worth in terms of knowledge, skills, or competencies. In his grand, classic survey *Prestige, Class, and Mobility*, sociologist Kaare Svalastoga (1914–97) stated that achievement factors rooted in the passing of some formal or informal assessment are predominant among a society's status determinants (Svalastoga, 1959, see also Weber, 2009). Through this lens, educational assessment is closely associated with the societal, and bureaucratic, division of labor as a provider of formal certifications, but also serves certain ideals and ambitions within both society and individuals, such as the strive for meritocracy and status.

Both these bureaucratic and idealistic layers of educational assessment interact with an economic approach to education whereby education is seen as a key production factor in the pursuit of economic growth (Spring, 2015; Ydesen and Bomholt, 2020). In the language of human capital theory, education assessment systems act as gatekeepers to a hierarchy of education qualifications and thereafter training and employment opportunities. Credentialism holds increasing value in the labor market, i.e. the strive for elite status in a market of professions (Collins, 1990). The idea is that education in general and credentialism in particular will lead to increasing productivity benefitting both the individual and society (Brown et al., 2020).

At the same time, however, the same bureaucratic and idealistic layers also intertwine with citizenship education where ideals about democracy, participation, human growth and enlightenment take pride of place. Viewed in a historical perspective, the building of education systems in general, and assessment systems in particular, has been closely wedded to constructions of

¹It should be duly mentioned that the architects of IQ testing in the interwar years worked from the assumption that IQ testing would be an objective scientific tool for engaging in social engineering activities with the promise of optimizing society and putting everyone in their "right place" (Chapmann, 1988; Ydesen, 2011). In this sense, there was a distinct prognostic component associated with IQ testing.

nationhood, states and ultimately nation-states through the fabrication of the model national citizen (Tröhler et al., 2011; Tröhler, 2020; Popkewitz and Lindblad, 2004).

Following an exploration of some of the most pregnant scholarly debates in education assessment, it is the purpose of this chapter to unpack some of these complex layers, and their interwovenness, while unraveling the assumptions, preconditions as well as the possibilities and limitations of the possible research paths for exploring the phenomenon of education assessment. Finally, the chapter outlines some of the implications for policy and practice in a concluding discussion.

Scholarly debates in educational assessment

Educational assessment is a research topic which sometimes creates polarizations and acrimonious debates in the scholarly field (Baird and Elliott, 2018; Garsdal and Ydesen, 2009). The contentious nature of researching educational assessment can be explained as a result of at least three interconnected factors which have to do with the practical enactment of assessment and assessment research.

The first is that a wide array of research fields are engaged with research on educational assessment from psychometrics, psychology and sociology to history and political science. These fields often subscribe to different philosophies of science, and they have diverse traditions in terms of methodology, theory and even the purpose of research. These research fields often also publish their research in different journals which means that much research on education assessment “runs” in parallel paradigmatic strands which tend to reproduce the polarization.

The second factor is that something is generally “at stake” in educational assessment. Different stakeholders – for instance, students, parents, teachers, school leaders, local authorities, national authorities, edu-businesses and global actors – have different interests and priorities when it comes to educational assessment and that has an impact on the field in terms of *which research* is used for *which purposes* and, even, sometimes, which types of studies get funded.

The third factor relates to the different understandings of the nature and purpose of education and therefore educational research (Lagemann, 2009). According to Biesta (2015), there is a division between education researchers “who approach education first and foremost in technological terms – that is, as an activity or practice that is ultimately understood as being governed by cause–effect relationships (...) – and those who see education first and foremost as a human event of communication, meaning making and interpretation in which questions of cause and effect actually have no place.” (p. 12; see also Lagemann, 2009). To a large extent we can recognize the economic – i.e. an applied – approach versus the citizenship – i.e. a *Bildung* – approach to education mentioned above in Biesta’s distinction.

On a more philosophical level, the contentious nature of research on educational assessment surfaces in three key issues. The first is whether educational assessment can be viewed as an isolated phenomenon or whether it must be viewed in connection with other aspects of education (Baird et al., 2017; Hegarty, 2020). This issue is very clear if we look at research critical to assessment practices where a clear line between endogenous and exogenous critiques is visible. Endogenous critiques claim that problems with education assessment can be remedied if better methodological tools and procedures are used. This kind of critique often comes from within the ranks of psychometrics and psychology (e.g. Allerup and Kjeldsen, 2017). Exogenous critiques on the other hand argue that education assessment tools and practices must be viewed in their context and that they are essentially flawed, skewed and beyond repair (e.g. Au, 2009). This kind of critique often comes from sociology and various sub-disciplines of history (e.g. Danziger, 1990; Simon, 1953).

Another related issue is whether educational assessment is a neutral or normative undertaking. In other words, whether assessment tools provide a neutral and objective snapshot of a student’s proficiency level or whether assessment tools are essentially filled with values and normativity by default. For instance, certain studies point to the existence of class assumptions about merit and ability (e.g. Stobart, 2008) whereas others highlight the objectively beneficial contributions of assessment to education in a wider sense (e.g. Phelps and Gottfredson, 2009; Roediger et al., 2011).

A third issue pertains to the purposes of assessment. Here it is commonplace to find conceptual distinctions between summative and formative types of assessment whereby the former is defined as end-of-process evaluations and the latter as in-process evaluations. Newton (2007) has problematized the formative versus summative distinction arguing that there are many distinct assessment purposes and not just two broad categories. Thus, this dichotomous vocabulary runs the risk of blurring and reducing our understanding of how assessment actually works in practice.

Given these issues and the contentious nature of educational assessment, it is possible to use a key issue as an illustrative case for teasing out the assumptions and preconditions associated with research approaches in educational assessment which serves as a foundation for understanding implications for policy and practice in the final section of the chapter. It is the purpose of the next section to explore how different research approaches have dealt with the question of how to balance human diversity and standardization within an educational assessment system.

Research approaches to educational assessment

It is often said that research findings and knowledge creation depend on the questions, assumptions and approach taken at the outset to the study. Research in educational assessment is no exception. As already implied above, it is possible to discern two

overall different methodological paradigms in educational assessment research: (i) an empirical positivist approach based on findings drawn from measurement data and (ii) a sociologically oriented approach incorporating the human, cultural, historical, conceptual, and technical dimensions of assessment (Andreasen et al., 2013).

The “positivist” paradigm is often guided by an applied, “what-works”, and all-other-things-being-equal approach to research in educational assessment. The research questions occupying this paradigm are typically concerned with how assessment data can provide insights into how students learn, how learning processes can be optimized, and what works for teachers. It often pursues the ideal of educational contexts as laboratories from which data can be extracted and improve our practices and policies. Some of the fields most keenly engaged in this paradigm are education economics, psychometrics, behaviourist psychology, and quantitative-statistical parts of evaluation research and political science.

The “sociological” paradigm is generally guided by an ambition to contextually decipher the meanings, workings and implications of educational assessment and sometimes even to de-naturalize the natural in order to gain new insights. It is in this tradition that we find a number of research agendas, such as critical policy analyses, and the ambition to unravel power compositions in education contexts. Some typical research questions pursued in this paradigm explore constructions of normality and deviance in education, the reproduction of inequalities, and the cultural and/or material factors affecting assessment performance and practice. Some of the fields most keenly engaged in this paradigm are critical sociology of education, critical policy research, science and technology studies (STS), new materialism and international political economy.

Turning to attempts to balance human diversity in the classroom with standardization of assessment practices, it could be claimed that the challenge lies in the fact that assessment technologies are often used to categorize, rank and standardize students in relation to predetermined categories and/or learning goals. Education assessment practices, to a very large extent, determine which students are actually “good enough” to contribute in “the right way” to educational activities and demonstrate “visible” learning progression. On the other hand, human diversity means that idiosyncrasies, individual preferences, interests, talents, attributes and abilities make it difficult to standardize the educational performance of individual human beings. Some students will thrive in certain learning environments and excel in certain forms of assessment, whereas others will not. As emphasized in UNESCO’s Global Education Monitoring report 2020 on inclusive education, all students are potentially at risk of education exclusion, depending on the context and content of the learning environment (UNESCO, 2020).

In the “positivist” paradigm, the ambition and the belief are that the human diversity-standardization issue can be overcome by means of an ontology of objective domains such as particular skills, attributes and abilities. It means that assessment technologies generate an extrapolation of a student’s constructs – e.g. intelligence, competence, ability, functional literacy – in relation to the domain being assessed. As pointed out by Madaus et al. (2009), the domains for many high-stakes tests “are defined by the standards or curriculum frameworks established by state departments of education.” (p. 39). Since domains are fixed targets, it makes sense to assess students in relation to these domains. It requires the construction of valid and reliable assessment tools. When these tools have been developed, the assessment results will reflect student diversity and the assessment results yield useful data for the construction of hypotheses and interventions that may help to alleviate politically defined problems in education like closing the attainment gap and optimizing learning environments. In this paradigm, assessment technologies are part of the solution.

In the “sociological” paradigm, domains, constructs and student abilities are moving targets and, as I have already implied, the focus is fundamentally different. Assessment technologies are seen as having the potential to be a significant co-constructor of differences between pupils, and thus also for the construction of the way in which these differences are understood by both teachers and other actors in education, such as parents, headteachers, etc. (Feniger et al., 2016; Kelly et al., 2018). These are the so-called backwash effects (Madaus, 1988). From an STS perspective, Addey and Gorur (2020) argue that the preparation and implementation of assessment technologies often rests on a significant reduction of complexity. They argue that the process constantly considers how reality can be reconciled with the assessment design. This creates a design space containing certain technologies and tools, but also political ideas, understandings and priorities, which cannot in any way be described as objective and which affect understandings of normality and deviation, as well as good and bad results. The “sociological” paradigm often demonstrates how educational assessments can lead to negative practices, such as selective admission, off-rolling, strict discipline policies, student reassignment and greater focus and time given to those most likely to succeed. Through this lens, assessment technologies are often seen as part of the problem.

Concluding discussion: implications in terms of policy and practice

It hardly comes as a surprise that the policy and practice implications associated with these two paradigms are very different. While one paradigm seems to suggest that data, numbers, and results constitute a possible and feasible way to run and develop an education system, the other paradigm seems to promote a much more contextual understanding. Here structural explanations and the unraveling of suboptimalities, like counterproductive mixes of performance indicators, and contra-finalities, like plagiarism, off-rolling and practices of gaming the system, take center stage (Baird and Elliott, 2018). It even adds to the complexity that policy and practice also must take into account the layers of educational assessment arising in relation to different stakeholders, instruments and purposes mentioned above. There are no quick fixes in educational assessment.

In order to provide policymakers and practitioners with an appropriate level of agency allowing them to create good and relevant solutions in the context in which they operate, it is essential that they are aware of the assumptions, outlooks, limitations and explanatory power provided by different types of assessment research. No research is value free and devoid of normativity even

though it may be cloaked as such. Stakeholders need to be empowered to judge whether the policies and practices which develop from various types of assessment research are relevant in the given context and under which conditions the research findings are appropriate. At the training level this requires a certain level of data and assessment literacy among stakeholders and practitioners, but it also requires awareness of the mechanisms, agendas and interests promoting different types of assessment research and assessment data. It is essentially about the politics of policy and practice (Ozga, 2020). The development, implementation and enactment of educational assessment never takes place in splendid isolation and education research in a wider sense has a big task in creating awareness among stakeholders.

In his musings on policy implications, Newton (2007) suggests that the design of an educational assessment system must lay bare and make transparent to all stakeholders those purposes for which assessment results are fit and those for which they are unfit. A good assessment technology in one area may be harmful in another area. Newton argues that “stakeholders should be deprived of ignorance as an excuse for misuse.” (p. 168). Another useful approach to working with assessment implications in terms of policy and practice comes from Stobart (2008) who argues that the three best questions to ask of any educational assessment are (p. 14):

1. What is the principal purpose of this assessment?
2. Is the form of the assessment fit-for-purpose?
3. Does it achieve its purpose?

On a deeper level we might even ask how educational assessment came to be seen as a “problem” for governments and other experts to address. Asking this sort of question connects with the question of how it is possible to establish fairness and credibility in an assessment system (Nisbet and Shaw, 2019). The issue here is to balance ideals about assessment technologies being “free from bias, and ideally fit all test-takers, independent of their gender, race or socio-economic background” (Hopfenbeck, 2019, 537) and trustworthy so that they are able to fill the function that society expects of them. This question cuts across the two paradigms. But while the “positivist” paradigm tends to emphasize how assessment systems can offer fairness and credibility – typically from a technical-methodological angle where validity, reliability and transparency are the core ideals –, the “sociological” paradigm tends to focus on the deprivations of assessment by focusing on the hidden curriculum, the reproduction of social inequalities, governance issues and the role of political interest.

In an attempt to strike a balance between these perspectives, UNESCO emphasizes how “Assessment should be formative and allow students to demonstrate learning in a variety of ways.” (UNESCO, 2020, p. 21). It means that it must be possible to identify and recognize all students’ progress and achievement in order for all students to be able to demonstrate what they can do without any exclusionary consequences.

Nevertheless, it is important to take into account the inertia of educational assessment systems. The logics and styles of reasoning surrounding and driving educational assessment policies and practices tend to reproduce themselves. For instance, in 2013, following critiques of the OECD Program for International Student Assessment (PISA) by Professors of Statistics Svend Kreiner and Karl Bang Christensen (Kreiner and Christensen, 2014), the Danish Minister of Education, Christine Antorini, stated that international ranking of education systems based on PISA-data was meaningless. But this important reservation had already been forgotten by the time of the next PISA-round. The inertia may be explained by a “fear of falling behind” among PISA participating nations (Krejsler, 2019). It is a strategic development narrative about world order dictating that nation-states will lose the global competition between knowledge economies, if they fail to optimize their human capital, i.e., produce “employable” or “career-ready” adults who participate in the economy (see also Grek, 2009).

Another explanation comes from an increasing trend among policy makers to intervene in education practices in the interests of policy objectives such as efficiency, reform, modernization, globalization and competition. Pasi Sahlberg has described this development as the Global Education Reform Movement (GERM). GERM is an education reform approach that broadly follows the tenets of postwar neoliberalism and especially 1980s New Public Management (Fuller and Stevenson, 2019, see also Hill and Kumar, 2009; Verger et al., 2018). It is structured around a common set of policy ideas, including standards-based management, performance evaluation, accountability demands and evidence-based policies, all of which thrive on assessment data.

Such inertia in educational assessment again calls for greater awareness among stakeholders as argued above. Allowing a senseless and unreflective reproduction of educational assessment policies and practices runs the risk of creating systems unfit for human lives. Instead, decision-makers at various levels of education systems must take the lead and make wise decisions by asking questions such as: What should be the consequences for students associated with different forms of assessment? What is the level of flexibility in the system? How can everyone achieve positive destinations and recognition? Such questions require also reflections on what degree of standardization is actually required in different assessment tools, how educational assessments should be designed given the culture and values of the context, and what needs to be controlled and what can be left to trust (Lillejord, 2020).

Education has the potential to serve as a driver for enabling social and economic development and reducing systemic inequality. Governmental policy makers must establish educational priorities in response to complex and critical societal challenges in an ever-changing landscape. Education policy makers have focused on policy reform efforts to improve the quality of education and supply a workforce for economic development (Barone and Ruggera, 2018; Sahlberg, 2016). Market system priorities are often reflected by competing political priorities entangled into national educational policies. National assessments are viewed as mechanisms for achieving broad policy goals, such as improving the labor market, promoting equity, and learning outcomes, or having an informed citizenry (Sahlberg, 2016), although such policies may not prioritize equitable educational outcomes for all learners (Sant, 2019).

Globally, educational reform has been articulated by “three policy principles: accountability, standards and decentralization” (Verger et al., 2019, p. 7). Decentralization is the use of national assessment results to control state, regional and local authorities often reflected by the tensions between national and local priorities. Reviews of international assessment policy and practice often highlight a tension between formative and summative purposes of assessment (also known as assessment *for* and assessment *of* learning), and the ways in which assessment policies can have unintended consequences (Birenbaum et al., 2015; Högberg and Lindgren, 2020; Verger and Parcerisa, 2018; Ydesen and Bomholt, 2019). However, some countries have managed to maximize the positive benefits of external accountability assessment through sampling approaches and careful attention to assessment timing (Heritage and Wylie, 2013; Volante et al., 2020). Every country’s accountability system has unique features and the nuances that come from understanding the context in detail are important. We examine educational policy and accountability assessment practices in the United States (US) during the first two decades of the 21st century in detail as a case study of how policy can achieve some of its initial goals as well as the unintended consequences that can emerge.

The assessment landscape in the US

During the first two decades of this century in the US there have been two significant acts of federal legislation, the *No Child Left Behind* Act of 2001 (NCLB; Public Law No. 107-110, §115, Stat. 1425, 2002) and its successor, the *Every Student Succeeds* Act of 2015 (ESSA; Public Law No. 114-95, §114 Stat. 1177, 2015). These legislations represent educational law for public schools in the US and provide the requirements for how state-level departments of education establish standards, administer annual standardized assessments, and implement accountability requirements. Both Acts resulted in considerable changes to how accountability assessments were conducted across the nation. NCLB mandated that summative assessments be administered to all students annually beginning at third grade, with sanctions imposed on schools that failed to meet established achievement targets. Under ESSA some of the sanctions were reduced, but state-level accountability assessments remained as a central component of the legislation. In sections that follow we examine these two Acts in more detail and the impacts that they had on teaching and learning in the US.

The reauthorization of the Elementary and Secondary Education Act in 2001 under the NCLB required states receiving Title I funding¹ to participate in National Assessment of Educational Progress (NAEP) reading and mathematics assessments. The

¹Title I funding comes from the federal level Department of Education to local educational agencies for children from low-income families to help ensure that all children meet challenging state academic standards.

NAEP is administered by the National Center for Education Statistics (NCES) within the U.S. Department of Education and the Institute of Education Sciences (IES). NAEP is a congressionally mandated project administration of assessments, generally on a 4-year cycle, in a variety of subjects. Results from the mathematics, reading and science assessment are perhaps the most often cited, but other content areas include civics, geography, US history, and technology and engineering literacy. Representative samples of students are assessed in each administration, and the results have provided longitudinal measures of what students know and can do at the national and state level. However, the NAEP assessments are not used as state accountability measures nor do they have sanctions associated with them, like the state-required assessments that followed the NCLB and ESSA legislations.

In the US, the regulation and governance of education systems is enacted at the state and territory levels. Rather than using sets of national standards, the 1990s saw each state create their own standards, and revise them after NCLB was enacted. Thus, accountability assessments are also state-specific rather than nationally administered. The closest that the US has come to national standards has been the Common Core State Standards (CCSS) in mathematics and English language arts, released in 2010 and adopted by 45 states and the District of Columbia. Although the CCSS initially were viewed as strong standards that almost all states could support, adoption of them became a political issue and since then 24 states have revised their standards (Coe and Daugherty, 2017; Evers, 2015). The introduction of the Next Generation Science Standards in 2013 have been adopted more slowly, with 19 states to date having signed on. During NCLB, a significant move away from the model of every state developing its own accountability assessments was initiated in 2009 through a federal grant competition (Race to the Top) that included encouragement of the adoption of the CCSS and support for the development of common state assessments by requiring consortia to establish a common cut score for all consortium states (Hain and Piper, 2016).

In addition to state autonomy, many school districts also function largely independently, described as “local control” which means that state departments of education can make recommendations, but not mandate decisions about curriculum or assessment at the local level. As a result of this devolved approach to education, while almost all students within a school district will take several state-determined accountability assessments each year, most assessments (e.g., classroom summative, interim, diagnostic) that students complete will be determined locally, either at the district or school level.

The No Child Left Behind Act of 2001

One motivation that informed the *No Child Left Behind* Act of 2001 was the need to close achievement gaps among groups of students, and the very title of the Act was intended to serve as a clarion call to act to meet the needs of students of color, and students from economically disadvantaged families, English Learners (ELs) and students with disabilities. The Act was intended to create increased accountability for assessment results, greater flexibility at the state and local levels to reduce bureaucracy, greater choice for parents of children who are attending failing schools, support for early grade reading, and a focus on improving teacher quality.

During the 1990s states had put in place accountability testing of students in at least fourth and eighth grade (U.S. Department of Education, National Center for Education Statistics, 2003). NCLB mandated that states had to adopt challenging academic standards and that student progress and achievement must be assessed annually in reading and mathematics from grade three through eight and once in high school. The data from these assessments, including results disaggregated by race, gender, and other criteria, were to be made publicly available to support comparisons across schools and districts.

One of the least realistic requirements of NCLB was that all students demonstrate proficiency on state standards by the year 2013–2014, as measured by the state assessments, and that schools make improvements toward that goal each year. While this was a federal mandate, each state had the freedom to decide what assessments to use and where to establish the bar for proficiency. School assessment results were then tracked to determine whether students were making progress toward achieving proficiency goals. Failure to meet these goals for 2 years in a row, described as “not making adequate yearly progress (AYP),” resulted in an escalating series of school sanctions, up to school closure. Accountability assessment results were reported by various subgroups (major racial/ethnic groups, students with disabilities, economically disadvantaged and ELs) which drew attention to schools that had overall strong student performance, but where the average results masked significantly lower results for subgroups of students (Hakuta, 2011). However, one challenge with the requirement of 100% of students demonstrating proficiency was that progress had to be made for each reportable subgroup of students. Schools with the most diverse student bodies would have to meet the AYP for every subgroup which penalized schools based on individual school demographics. In the next section we focus on students with disabilities and ELs given how NCLB regulations interacted with other federal policies.

NCLB and special populations

NCLB aimed to ensure that all children have a fair, equal, and significant opportunity to obtain a high-quality education and reach, at a minimum, proficiency on challenging state academic achievement standards on state academic assessments. One federal policy that intersects with NCLB’s assessment and accountability provisions is the Individuals with Disabilities Education Act (IDEA, 2004), originally enacted in 1975 as the Education for All Handicapped Children Act assured that a free and appropriate education is made available for all students with disabilities and established, to the maximum extent appropriate, that students be educated in the least restrictive environment to the extent possible, thus raising expectations for students with disabilities.

IDEA (2004) requires all students with disabilities receiving special education and related services have an Individualized Education Program (IEP). Each student’s IEP outlines the specially designed instruction necessary to provide full participation and access to the general curriculum and how students participate in state assessment (NCLB, 2002). Students with disabilities are included on

state assessments, with or without accommodations (i.e., changes made to the assessment itself or additional supports or services that allow students with disabilities to demonstrate their true knowledge, skills, and understandings on the assessment without being hindered by issues of accessibility), and students with the most significant cognitive disabilities may need alternate assessments (NCLB, 2002). NCLB regulations allowed alternate assessments to be based on either alternate academic achievement standards (AAAS) or modified academic achievement standards (MAAS). For accountability NCLB regulated states to the number of students enrolled in the tested grades for alternate assessment based on AAAS at one percent and alternate assessment based on MAAS at two percent (U.S. Department of Education, 2007). Alternate assessments based on the MAAS were later eliminated based on research that demonstrated that students with disabilities who struggle with reading and mathematics can achieve at grade-level standards if provided “appropriate instruction, services and supports” (U.S. Department of Education, 2015). IDEA (2004) requires every state to establish guidelines for accommodations to make sure that students use only accommodations that produce a score that is valid for school accountability purposes.

NCLB mandated the inclusion of all students in the state accountability system. In response to NCLB, students with disabilities with IEPs were expected to reach the same level of performance as all other students participating in the general curriculum. IDEA requires every state to establish guidelines for accommodations to make sure that students use only accommodations that produce a score that is valid for school accountability purposes. IDEA (2004) and accountability requirements served as a mechanism for change in raising expectations, gauging the progress of students with disabilities, and improving opportunities for access to the general classroom which have improved dramatically in the years since *No Child Left Behind* was implemented, as will be described below (Cole, 2006; Hardman and Dawson, 2008).

The law required the inclusion of English language learners in state assessment mandates and accountability systems; accordingly, these students were expected to make annual progress as measured on standardized tests of both English language proficiency and academic content. Under NCLB states are required to establish English language proficiency (ELP) standards and to use a single ELP test to assess students’ progress in and mastery of these standards in four domains: reading, writing, speaking, and listening (Fast et al., 2004). Prior to NCLB, English language proficiency (ELP) assessments were of poor quality in terms of content and psychometric properties (Abedi, 2008). NCLB regulations increased national awareness of ELs as a diverse and growing population, while also disproportionately labeling them as failing under NCLB accountability policies.

NCLB defined ELs as Limited English Proficient (LEP). States were required to include English language proficiency in their accountability systems including requirements for monitoring ELP progress and achievement through Annual Measurable Achievement Objectives (AMAOs). NCLB led to the termination of the Bilingual Education Act, which was replaced with the Title III,² the English Acquisition, Language Enhancement and Academic Achievement Act, which further emphasized English learning and removed the term bilingual from federal law. While states developed ELP standards, the mandate allowed local entities to choose the method of instruction was to be determined at the local level. Policies for improving English language acquisition did not address how to support the inclusion of ELs in standards-based instruction and failed to recognize the national emphasis on high stakes testing often led to teaching methods were ineffective for meeting the needs of ELs, such as a focus on test preparation (Menken, 2008). ELs disproportionately attend high poverty schools with limited resources and were unprepared to meet AYP expectations (Fry, 2008).

Every Student Succeeds Act of 2015

NCLB was in place for 14 years, despite significant criticism elaborated on below, to be replaced by the *Every Student Succeeds Act* (2015). Under ESSA, greater flexibility was granted for State and local education leaders to do what is best for children, while protecting historically underserved students. The state retains authority and flexibility to set goals within the federal framework (Saultz et al., 2017). The ESSA is clear that the role of the federal government would not “influence or incentivize” educational policy and specifically stated that authority would be up to individual states including the adoption of academic standards (ESSA, 2015, p. 130).

Specific areas of flexibility under ESSA include exempting eighth grade students from the mathematics assessments if the student takes an end of course assessment administered in high school for accountability purposes (ESSA, 2015). A State may permit its districts to administer a selected, nationally recognized high school academic assessment in place of the academic statewide assessment recognized by higher institutions of education for the purposes of entrance of placement in courses in postsecondary education or training programs. To encourage innovations in assessments systems, states may also apply to the Department of Education to pilot new approaches in some of its districts instead of using statewide assessments.

In some ways the ESSA did not make significant changes in that states must still conduct annual assessments in mathematics and reading from grades three to eight and once in high school, along with testing science once per grade band, in elementary, middle, and high school. Students with the most significant cognitive disabilities may be tested on alternate achievement standards (AAAS) aligned to grade-level and state standards. ESSA provides that states may have one percent of accountability testing to include students identified as having the most significant cognitive disabilities. ESSA, for the first-time required states to submit their state English language proficiency assessments, which includes alternate English language proficiency assessments for ELs with the most

²Title III funding is provided by the Department of Education to local educational agencies to help ensure that English learners (ELs) attain English language proficiency and meet state academic standards.

significant disabilities to the U.S. Department of Education for federal peer review³ (U.S. Department of Education, 2018). Flexibility is given whether to include recently arrived ELs who have been enrolled less than twelve months into state testing requirements. Under ESSA, reporting on state assessments has expanded significantly from the NCLB categories to also include children of military parents, foster children, homeless students, migrant students, gender categories, school quality, climate, and safety data, teacher equity data and per student expenditure data.

Under ESSA, funding flexibility has increased to provide resources to states and school districts to establish, implement, and sustain high-quality instruction designed to ensure that ELs develop both English language proficiency and content proficiency in math, English, and science. Additionally, states could create individual statewide accountability systems by developing plans which identify schools that are underperforming and how to support schools in getting them on track. States now establish achievement targets, and rather than federal penalties for struggling schools, schools will receive additional funding and support. States have significant discretion with respect to the funds that it must reserve to support school improvement activities in schools needing comprehensive or targeted support and improvement and for the State's statewide system of technical assistance and support. The State can distribute funds on a formula or a competitive basis, which may have impact on underperforming schools. Federal regulations also require that State accountability measures must include four academic factors: test scores for reading and math, English language proficiency test scores, high school graduation and a state-chosen academic measure for grade and middle school. States may choose a factor that affects school quality such as, kindergarten readiness, access and completion of advance coursework, college readiness, school climate or absenteeism.

Positive impacts of federal assessment policies

NCLB and ESSA have had several positive impacts on teacher qualifications, parent information, curricular alignment, student learning, and particularly on special populations, although as will be described below some of these positive impacts were relatively minor.

One requirement of the NCLB legislation was that core academic classes were to be taught by "highly qualified" teachers which was defined as having a bachelor's degree, being fully certified, and demonstrating their knowledge and skills in the subjects they teach through sufficient subject-matter coursework, passing a state test, or meeting other state criteria. The Center on Education Policy conducted a nationally representative survey of 349 school districts, between November 2006 and February 2007 (McMurrer, 2007), with one aspect of the survey focusing on changes to teacher qualifications and the perceived impact on student learning outcomes. One contradiction in the results is that while most districts were moving toward compliance, the majority of state and school district officials did not believe that the changes were having any impact on either teacher effectiveness or student learning outcomes (McMurrer, 2007). Less than ten percent of states or districts indicated that the law's requirement had improved student learning or teacher effectiveness to a great extent. Most districts indicated that they would be in compliance with the requirements by the 2006-07 school year, although some doubted that they would ever be given persistent staffing challenges. The lack of perceived impact of these requirements stemmed from the view that the NCLB definition of a highly qualified teacher was too narrowly focused on content knowledge rather than additional pedagogical competencies such as the ability to differentiate instruction to meet student needs (McMurrer, 2007). While there the proportion of teachers' meeting the standard of "highly qualified" improved, it was not a highly valued change given the focus on qualifications rather than a focus on teacher learning of critical teaching practices.

A second impact from increased use of accountability assessments and disaggregated reporting was that parents and other stakeholders had greater access to information about student learning outcomes, which could be compared to outcomes of other students within the school, district, and state. It is notable that across several different studies African American and Hispanic parents placed a greater value on standardized tests and their reports than White parents (e.g., Brewer et al., 2014; Phi Delta Kappa and Gallup, 2015; Tompson et al., 2013). Tompson et al. (2013) found that not only were parents of color more likely than White parents to think that it was important or extremely important to regularly assess whether students are meeting statewide expectations, similar differences were found when survey respondents were grouped by income with lower income parents responding more favorably to the importance of assessing whether students are meeting statewide expectations. Their report does not attribute reasons for the different attitudes among racial/ethnic or income groups, but in part it is likely a recognition that if disparities are not identified, they cannot be remediated.

A third area of practice affected by NCLB that was English language arts (ELA) and mathematics curriculum alignment with standards and with state assessments. A study by the Center on Education Policy, using a representative survey of 349 school districts, indicated that almost all the surveyed districts had required curricula for ELA and mathematics for elementary, middle, and high schools, with the majority reporting that it was aligned or very well aligned with the state assessments (McMurrer, 2008a). The study included case study reports from districts that provided examples of how districts had adopted standards, reviewed, and revised curricula, and created supporting documentation to help teachers (McMurrer, 2008a). A later study (Polikoff, 2012), using data

³The Peer Review process was first introduced as part of NCLB and required state departments of education to submit a report with documentation about the quality of their accountability assessments in mathematics and ELA based on peer review standards to a national panel of experts.

from the Surveys of Enacted Curriculum (SEC) found evidence of small to moderate changes in alignment between standards and reported classroom instruction, with the largest and most consistent increases in mathematics.

The fourth area of impact of NCLM was on student outcomes. In a study using NAEP data to examine the impact of the introduction of accountability systems on student outcomes pre-NCLB, [Hanushek and Raymond \(2005\)](#) concluded that the combination of reporting accountability assessment results together with school sanctions had an impact on student learning outcomes. One of the most thorough examinations of the impact of NCLB on student learning outcomes is the emphasis on data collection and examination of results from multiple data sources to gather evidence for accountability ([Dee et al., 2010](#)). To examine the impact on student learning outcomes the authors used data from the National Assessment of Educational Progress (NAEP) to examine national trends over time and to compare results for states that had previously more NCLB-like accountability requirements with those that did not. They also drew on data from international assessments, Trends in International Mathematics and Science Study (TIMSS) and Progress in International Reading Literacy Study (PIRLS). From these various studies they concluded that NCLB had a positive impact on student performance in mathematics, particularly at lower-grade levels, and for traditionally disadvantaged populations, although there was not a comparable effect on reading ([Dee et al., 2010](#)). Another study ([Lauen and Gaddis, 2012](#)) examined the impact of NCLB specifically on the performance of subgroup performance in schools where that subgroup failed to meet AYP the previous year. They reported similar findings, although found improvements in both mathematics and reading, with small improvements for Black and poor students and greater improvements for Hispanic students. Moreover, this effect was stronger for schools where the subgroups were further from proficiency than those that were closer.

Benefits for special populations

In a descriptive study of twelve states [Harr-Robins et al. \(2015\)](#) examined the inclusion of students with disabilities into accountability systems under NCLB. Schools in each of the twelve states' accountability system identified as "consistently accountable" were compared to schools identified as "never accountable." They found that in schools identified as "consistently accountable" the number of students with disabilities moving from self-contained settings to regular classrooms increased in elementary schools (15.8%) and middle schools at (16.7%). Schools identified as consistently accountable were found to be more likely to implement highly effective practices such as, adopting reading and mathematics programs, supplying more instructional time and support, using assistive technology, and implementing positive behavior support programs ([Harr-Robins et al., 2015](#), p. 8).

ESSA (2015) requires that all students, including students with disabilities, have access to an appropriate education that will prepare all students for college and career readiness ([Tomasello and Brand, 2018](#)). Under ESSA, supports for students with disabilities have included support for universal design as a technical requirement for designing state assessments. The expansion of personalized learning to support individual needs of learners and the identification of projects and programs to support special populations and districts using the flexibility in funding ([Cook-Harvey et al., 2016](#)). Under ESSA, flexibility in funding provided professional development to support educators in meeting the needs of students with disabilities and ELs, led to class size reduction and increased mechanisms to engage parents, families, and communities.

As a result of ESSA, which emphasized college and career readiness for all students, other regulations were written such as the Strengthening Career and Technical Education for the 21st Century Act (2018) which sought to reform the public workforce system. These regulations emphasize the importance of the education-to-workforce pipeline to provide individuals with the academic, technical, and employability skills they need to be successful in the workforce. These regulations support students with disabilities on their path to college and career readiness, postsecondary education, and employment which can lead to improving independence, self-sufficiency, and opportunities for competitive integrated employment ([U.S. Department of Education, 2014](#); WIOA (Workforce Innovation and Opportunity Act), 2014).

ESSA encouraged states to include college and career readiness indicators in their accountability systems. States track and report on such indicators which has also benefitted students with disabilities ([Tomasello and Brand, 2018](#)). ESSA flexibility provides additional resources for supports and services for students with disabilities to pursue their transition goals. Transition planning from high school to postsecondary education is required under [IDEA \(2004\)](#). ESSA flexibility in funding supports local educational agencies to provide transition services, which improves postsecondary outcomes for students with disabilities. While flexibility in funding and inclusion into state systems are important, it is reliant upon state and local leadership to make wise decisions about how programs are delivered to create career and technical educational opportunities for students with disabilities.

ESSA changed the way schools identify, serve, test and report information about students who do not speak English. ESSA establishes consistency in the identification of ELs and requires a uniform process for the identification of ELs to be created at the state-level. Under NCLB, district level approaches established their own processes and resulted in a variety of criteria for identification and exiting services. ESSA provided flexibility in funding to support EL (English Language) programs. Under the new reporting requirements, EL (English Learner) subgroups will be disaggregated and ELs with disabilities will be separated from the overall EL population. This disaggregation represents a crucial step in supporting investigations to understand the effectiveness of different supports and instructional models for ELs ([Burr et al., 2015](#)).

Under ESSA, federal assessment policies offer flexibility for local priorities. For example, the Seal of Biliteracy was not a direct positive impact of ESSA, but rather more indirect. Many advocates for bilingual education have criticized ESSA regulations for promoting monolingual deficit perspectives, which elevates English language acquisition and fails to value multilingualism ([Kim, 2020](#); [Harper et al., 2008](#)). A grassroots effort which values diversity and the multilingual language skills of many ELs has

brought about a movement for a Seal of Biliteracy (TESOL, 2015). The Seal of Biliteracy is a language policy initiative in 32 states that is an award affixed to high school graduates' transcripts and diplomas, to promote and foster students "bilingualism and biliteracy" for dual language learners in K-12 schools (Heineke et al., 2018.)

Negative impacts of federal assessment policies

As identified in the previous sections, NCLB and ESSA had several positive impacts on classroom practice in terms of alignment of standards and curriculum and classroom practice, although improvement in teacher qualifications was not viewed as impactful and impacts on student learning were modest at best and certainly not what were needed to reach the goal of one hundred percent student proficiency by 2013–14. Further, taken to extremes the benefits of alignment also resulted in distortions to teaching and learning. In this section we review these negative impacts.

One of the documented negative impacts that resulted from perceived or actual pressures resulting from pressures around accountability assessments included reducing or eliminating time spent on subjects that were not part of the accountability testing program, which essentially meant everything except mathematics and ELA, particularly in elementary schools. The nationally representative survey conducted by the Center on Education Policy conducted (McMurrer, 2008b) reported large shifts in instructional time in favor of English language arts and mathematics and decreases in time for studies, science, art and music, physical education, recess, or lunch. In their sample of districts, 58% and 45% reported increasing the amount of time in elementary schools for ELA and mathematics, respectively. For those districts that reported increased time, it amounted to an extra 141 minutes for ELA and 89 minutes for mathematics per week.

One study used surveys and case studies to collect data from teachers about their instructional responses to NCLB (Hamilton and Berends, 2006; Hamilton and Stecher, 2006). The researchers identified evidence of teachers making efforts to identify more effective instructional methods, they also identified large majorities of teachers reallocating time to spend more time on tested standards, using item types common to the state assessments and teaching test-taking strategies. They also found evidence of principals encouraging teachers to focus their attention on students close to meeting standards. This later finding was also identified by Nichols and Berliner (2008) noting that teachers in some schools were encouraged to focus on students who were closest to reaching proficiency and to ignore those who were further from meeting proficiency levels. At the most extreme end was the Atlanta Public School system cheating scandal that involved both principals and teachers changing student responses on NCLB assessments (Vogell, 2011).

Darling-Hammond (2007) described some of negative impacts on schools that resulted from the passing of the NCLB Act, drawing attention to evidence from states that had already imposed sanctions for schools not meeting standards prior to NCLB being enacted, suggesting that at least some of these negative consequences should have been anticipated. For example, schools that were rated as failing found it difficult to both retain their existing teachers and recruit new teachers, a pattern that had been previously observed in Florida prior to NCLB (DeVise, 1999). Second, schools that were not meeting AYP could potentially lose federal funding, had to fund transportation of students who wished to transfer out to other schools, and had to use twenty percent of their Title I funds for student services such as tutoring or after-school programs, resulting in failing schools having less money to spend on their students.

Negative impacts on special populations

The focus on accountability under NCLB illuminated achievement gaps for underserved populations (Reardon, 2011). The unrealistic expectations of one hundred percent student proficiency carried mandated sanctions which were ineffective in supporting goals of equal opportunity (Koretz, 2008). District administrators often blamed the assessment performance of students with disabilities as being the only factor that kept a school from reaching AYP. The failure of the special education subgroup to make AYP occurred mainly because the subgroup is expected to maintain the same proficiency levels as their general education peers, ignored the reality that students with disabilities are placed in special education because they have unique needs and require specialized instruction as documented by an IEP and therefore need more time to demonstrate learning. The students with disabilities subgroup began at a lower level of proficiency than any other subgroup and were unrealistically expected to achieve proficiency levels which required them to grow at a faster rate than their general education peers (Eckes and Swando, 2008).

In addition to a backlash against special education students and programs perceived as responsible for a school's failure to meet AYP, NCLB assessment sanctions led to a focus on state test performance results which resulted in a narrowing of the curriculum. A focus on accountability led to a greater emphasis on time spent remediating on standardized test content at the expense of other instructional priorities, students with disabilities received more time in pull out services for reading and mathematics basic skills and limited opportunities to enroll in vocational and career programs needed for post high school success (Olson, 2004). Accountability policies that are focused on reporting achievement gaps are unlikely by themselves to sufficiently strengthen academic outcomes of students with disabilities and improve their access to the general education curriculum (Gilmour et al., 2019).

High stakes state assessments and accountability systems place enormous political pressure locally resulting in many states sought methods such as lowering cut scores to facilitate the illusion of proficiency gains for students with disabilities and economic disadvantage (Koretz, 2008). Under NCLB there was a failure to set a consistent policy about the number of students needed in a subgroup for results to be reportable for that subgroup. As a result, states had significant variation in the rules for establishing

the number of students required for reportable subgroups and how students were included in the accountability system, which became a mechanism to manipulate proficiency numbers. Another mechanism to inflate proficiency rates is the process by which states establish cut scores on tests, setting expectations low and reporting results which mask a lack of progress in learning (Ho, 2008).

ESSA's limitations of federal authority and the increased authority of states to determine failing schools may not be any improvement over NCLB for students with disabilities and other vulnerable populations (Saatcioglu et al., 2021). Special education advocates have been concerned about the lack of federal guidance for state accountability under ESSA and are concerned whether state and local districts will lower expectations for students with disabilities and access to the general classroom will become more restrictive for students with disabilities (Adler-Greene, 2019; Edgerton, 2019; Gilmour et al., 2019).

NCLB assessment and accountability requirements for ELs exposed issues in identification, greater risk of disability representation, restrictive language policies, lack of quality programming and limited opportunity to learn (Gándara and Hopkins, 2010). Research on opportunity to learn for both ELs and students with disabilities has documented differential opportunities to receive quality instruction and services commensurate to non-disadvantaged peers (Burr et al., 2015; Kurz, 2011; Lopez et al., 2016; Pullin and Haertel, 2008). A lack of instructional time and content coverage has a direct impact on assessment results. An important yet often overlooked indicator of ELs' opportunity to learn at the secondary level is access to and completion of rigorous, college preparatory coursework (Callahan and Shifrer, 2016). Such indicators get at the heart of equity and systematically work to address disparities in achievement. While state tracking of EL progress may be included in some state longitudinal data systems, many data systems are not yet developed to track the nuances of EL data that might be important to capture opportunity to learn such as advanced coursework, years in program, reclassified ELs and dually identified ELs with disabilities.

Many proponents in the field of English learning viewed reporting mandates as unfair since accountability tests are primarily administered in English, and language proficiency impacts the performance of ELs. Unsurprisingly, ELs have consistently underperformed on these tests. Menken (2010) highlighted the impact on performance and the consequences of the mandates on English language learners (ELs) for participation in both English language proficiency and academic content assessments. Menken's position is that by subgroup definition ELs have not mastered the English language, and language proficiency impacts the performance of ELs on those assessments. Menken (2010) found linguistically complex English words, likely unknown by ELs, dominate high stakes content assessments. ELs who have been in the US for 1 year take the same English language arts tests as those taken by native English speakers. Menken further elaborated that performance data then documents inferior performance, which further disenfranchises ELs. Schools serving ELs are disproportionately penalized under NCLB as accountability requirements that expect ELs to make annual progress as measured on standardized tests of both English language proficiency and academic content only serve to further maintain the achievement gap.

ESSA provides flexibility in funding which can be used to address the recruitment and professional development needs of educators supporting ELs. ELs are an increasingly growing population, and the provision of services is complex. There is a growing need for professional development and a shortage of educators to serve ELs and provide quality programs (Arroyo-Romano, 2016; Wigan et al., 2020; Satcher et al., 2019). Under ESSA, Title III funding has increased to provide resources to states and school districts to establish, implement, and sustain high-quality instruction designed to ensure that ELs develop both English language proficiency and content proficiency in math, English, and science. Many states have not yet addressed teacher shortages and have little capacity to provide the professional development that would provide quality services.

Under ESSA, key decision-making is up to individual states. In this era of increased flexibility, it is possible for states to move from a governmental locus of controlled accountability to one of local authority (Edgerton, 2019). State leaders have expressed concern about how to meet requirements for English language learners and ELs with disabilities (Tomasello and Brand, 2018). How states define underperforming schools is critical and many states are establishing low criteria (Ushomirsky et al., 2017). Equity issues are deeply concerning for students in historically underserved communities, and especially for ELs, students with economic disadvantage, students of color, and students with disabilities who have the most to lose if the spirit of the legislation under ESSA is not achieved.

Impact of accountability assessments on teacher evaluations

In addition to impacting students through an increase in accountability testing, NCLB also shifted key aspects of teacher evaluations using student assessment data as a major component of those evaluations although it was not a direct requirement of the legislation. Rather, one of the requirements of the NCLB legislation was for every classroom to have a "highly qualified teacher." In 2002, the National Governors Association (NGA) published six strategies for policy makers to move their states toward achieving this particular NCLB goal (Goldrick, 2002). Policymakers were encouraged to consider taking legislative action to:

- define teaching quality;
- focus evaluation policy on improving teaching practices;
- incorporate student learning into evaluation;
- create professional accountability;
- train evaluators; and
- broaden participation in evaluation design (Goldrick, 2002, p. 2).

The use of student learning data as part of teacher evaluation was not a widespread practice in 2002 when it was recommended by the NGA and was initially slow to gain traction. In a study of state statutes and regulations, Hazi and Racinski (2009) reported on how states had begun to implement these NGA strategies. At the time of their analysis, all but eight states had adopted at least one of the NGA strategies, but the strategy of incorporating student achievement into teacher evaluation ratings had been adopted by only 12 states. However, this initiative received increased attention from the Obama administration (2009–2017) and the then Secretary of Education, Arnie Duncan (2009–2015). Thus, 2 years later the number of states that had passed legislation that would incorporate student achievement data into teacher and principal evaluations had jumped to 23 (Piro et al., 2011). This accelerated focus on the use of student achievement data in teacher evaluations was in large part due to a requirement for states applying for Race to the Top funding. State departments could apply for Race to the Top funding in order to support reform efforts focused on improving their assessments, turn-around of failing schools, supporting teacher improvement efforts and teacher evaluation processes. Eighteen states and the District of Columbia were awarded Race to the Top funding in three phases from June 2010 to December 2011. The use of student test scores as part of teacher evaluation was further incentivized by the requirement to include it as part of a state request for states seeking waivers from NCLB requirements (Close et al., 2018).

By the 2016-17 school year all but four states had implemented teacher evaluation reform, with the majority using classroom observation data as the biggest contributor to the overall evaluation, but with student test score data playing an increasingly significant role as a component of teachers' summative evaluation (Steinberg and Donaldson, 2016). Teacher evaluation, and specifically the use of student test scores, was still a highly controversial topic. Supporters of the process argue that it makes sense to include a measure of student learning as part of teacher evaluation (Goldhaber, 2002; Rivkin et al., 2005) while opponents argue that the measurement challenges render its use invalid (Baker et al., 2010; Braun, 2015; Papay, 2011).

The simultaneous introduction of new accountability assessments to evaluate student progress against newly adopted Common Core State Standards (or close variants of those standards) and the use of these data to evaluate teachers led to a very contentious reception for those assessments. The use of student test score data was often included in teacher evaluation systems using student value-added models (VAMs) which are complex, statistical models designed to measure how much value a teacher adds to (or detracts from) students' growth based on large-scale standardized achievement tests over each school year (Haertel, 2013). There were many highly publicized reports of teachers who were viewed by parents, administrators and peers as exemplary but were penalized unfairly because of student test results (Fairbanks, 2015). Further pressure on evaluation systems came from lawsuits at the state and federal level which claimed that these systems violated teachers' constitutional rights, especially in systems that used student value-added data models as significant factors in high stakes decisions about teachers (Pullin, 2013; Sawchuck, 2015).

NCLB reforms heralded the widespread use of student test scores in teacher evaluations, holding the view that improving teacher quality could erase the achievement gap (Haertel, 2013). Almost 15 years later, federal influence on teacher evaluation ended with the passage of the ESSA in late 2015, ending the federal definition of a "qualified teacher" and leaving it up to states to define. In addition, it became a state-level responsibility to establish criteria for teacher evaluations. An examination by Close et al. (2019) of these changes indicated that the use of student assessment results in value-added models (VAMs) as a component of teacher evaluation was becoming less popular although still used by a sizable number of states: 15 states (29%) reported use of VAMs in summative evaluations, two states (4%) used them formatively, and 10 (20%) states left decisions about their use to local school districts. One state was in the process of developing their system at the time of the analysis, and the remaining 23 states (45%) do not use VAMs. An in-depth evaluation by Mette et al. (2020) one year later however suggests that more states have shifted decisions to local districts about whether to include VAMs. Given how contested was the use of VAMs, there will likely be few teachers or school- or district-based leaders who will mourn their loss.

Impact of accountability assessments on the broader assessment system

One documented impact of increased attention paid to accountability assessments in terms of both school and teacher sanctions was the emergence of a new form of assessment, frequently called interim or benchmark assessments (Marsh and Robyn, 2006; Perie et al., 2009). These assessments are often purchased from a vendor and completed by the majority of students within a grade level so that comparisons can be made across classes or schools within a district. These assessments can be administered for instructional, evaluative, or predictive purposes (Perie et al., 2009). As schools were paying increased attention on meeting AYP, these periodic assessments provided a way for teachers and principals to have access to more frequent information about student learning. Some of these assessments are designed to provide common end-of-unit evidence of student learning that can be used to inform additional learning supports for specific students. However, some interim assessments are essentially mini-accountability assessments, used to predict student performance on the end-of-year assessments. The breadth of content coverage of these assessments reduces their likely instructional value and formative impact on student learning (Nabors Oláh, 2022). Paul Black observed the US assessment system over several decades and noted in the earlier nineties that "[h]igh-stakes testing can dominate classroom work and so distort teaching that the conditions for good formative assessment do not exist" (Black, 1993, p. 52). Almost 20 years later as NCLB was in full swing "These current dominant forms [of accountability] have undermined what should be the normal and healthy relationship between formative and summative assessment" (Black et al., 2011, p. 72).

The seminal report *Knowing What Students Know* (National Research Council, 2001) described a vision for assessments in which summative and formative assessment contributed various kinds of information for different purposes. The authors recommended that an assessment system should possess three essential characteristics to support student learning: comprehensiveness, coherence,

and continuity. These initial characteristics were subsequently augmented by Chattergoon and Marion (2016) to include efficiency and utility. However, creating a balanced assessment system that reflects a common understanding of student learning across components (comprehensive), that can provide evidence of student learning over time (coherent), that provides multiple opportunities for students to demonstrate learning (continuous), and that provides enough information for stakeholders without being bloated with redundant assessment (balancing efficiency with utility) is no small challenge. As previous sections indicated, the accountability assessments arising from NCLB and ESSA created challenges for teachers, principals and district leaders that resulted in assessment systems failing to meet all the criteria laid out for a balanced system. As noted earlier, teachers felt it necessary to change, some might say distort, what they were teaching to account for the end-of-year accountability assessments (McMurrer, 2008b), and concerns were raised by formative assessment scholars such as Heritage (2010) that too much focus on accountability assessment resulted in insufficient use of formative assessment.

Conclusion

The 2020-21 COVID-19 crisis introduced major upheaval in the US education system, which resulted in the suspension of the accountability assessment process for a year, so it is not yet readily apparent whether ESSA goals are to be realized. Challenges of access to broadband technology for digital learning have occurred for many students living in rural communities. The loss of teaching time has further disadvantaged students with learning and language needs and the impact of interrupted schooling is unlikely to be fully understood for several years. Accountability assessments for the 2020-21 school year were administered but the results were not used for accountability purposes given the huge variations, even within states and districts, in student opportunity to learn and technology access. As a result, there is currently much discussion about the implications for state accountability assessments moving forward. In the short term, state and district leaders are having to rethink what assessment data will be most effective to inform teachers about student understanding and how to support their learning moving forward. In several states this has resulted in a new appreciation for or understanding of the role of formative assessment to support student learning (Rathke, K., July 12, 2021, personal communication; Farley, D., July 12, 2021, personal communication).

As accountability assessments are being reconceptualized, it is important to recognize the complexity of educational systems. Desired changes within a system are best achieved when the intended purposes and goals of assessment are made explicit. One way that states might go about addressing these complexities is to develop a theory of action.⁴ The National Council on Measurement in Education (NCME) developed a position paper on theories of action, noting that they should include explicit identification of the assessment components and associated supports, the intended outcomes and the causal mechanisms expected to lead to those outcomes. Ideally the theory of action should also anticipate the ways that improper use of the assessment could lead to unintended, negative outcomes (NCME, 2018). The process of developing a theory of action supports transparency in goals and outcomes to help stakeholders know if they are successful, and for which learners. It also invites discussion about whether the action mechanisms are plausible in terms of leading to the desired outcomes. A review such as this could have created opportunities to raise questions about whether the NCLB focus on *teacher* quality, as described by qualifications, rather than *teaching* quality or sanctions on poorly performing schools, rather than additional supports, would result in the desired closing of achievement gaps. While hindsight is always clearer than foresight, we advocate for the development and critical review of theories of action as one mechanism that can support a system perspective on accountability programs.

Introduction

Educational assessment is often positioned as having three dimensions: policy, process and practice. These dimensions are not mutually exclusive but co-exist in relation to how assessment is considered within educational settings (the doing of assessment), but also how it is used systematically to be a major driver of educational change (the use of assessment). Assessment under these three dimensions is continually modified, adapted and adjusted to suit both pedagogical initiatives to enhance learning (see Mary James within this same publication) but also to advance political objectives. Assessment is used to drive policy imperatives within education more generally as a way of allocating resources (based on assessment outcomes) or cementing ideological directives through mandatory assessment of defined curricula and associated subject hierarchies. The consequences of these modifications, adaptations and adjustments to local, national and international educational assessment policy, processes and practices show assessment to be a much more complex socio-political phenomena than systems of neutral, technical evaluations of students' learning. Thus, for decades, across many jurisdictions and across many governments, assessment has been placed firmly within the education policy reform arena with all the subsequent turmoil that high profile policy focus can bring.

Another area of educational reform that has garnered more attention over recent years is that of "student voice" (Bourke and Loveridge, 2018). Cook-Sather (2006, 2018) has detailed the evolution of student voice in educational research that has, over time, repositioned the worth of students' unique perspectives on teaching, learning and schooling in general. Fielding (2001) suggests that the student voice movement can be seen as a partnership that has developed along a trajectory that has moved from students as a data source in early studies to students as active respondents, co-enquirers and co-knowledge creators. However, there has been considerable critique and debate about the capturing of student voice to inform educational policy and change practice. Lundy (2007) has argued that the inclusion of student voice is about more than just good practice; it is about children's rights. She is particular in arguing that fully embracing children and young people as key stakeholders in their educational experience and provision is rarely positioned by government in terms of children's rights. Under Article 12 of the United Nations Convention on the Rights of the Child (UNCRC), not only must governments consult children and young people in all matters that affect them (including education), but they must also support children's contribution to decision-making as well as listen to their views in constructive ways (Lundy 2007).

This chapter brings together these two seemingly disparate areas of educational interest, assessment reform and student voice. Rarely are the two areas considered as mutually enhancing, yet as we will show, there is a growing interest in how the practices of consulting young people about assessment matters and having them participate in the deliberations around national assessment policies can bring to the fore more radical ways of thinking about one of the most important activities in the educational lives of students. We begin by considering the policy landscape in education and assessment, together with research on student voice before discussing key messages and reflections that emerge when these seemingly disparate areas of educational interest are brought together.

Policy reform

Education policy reform

For many decades educational researchers have been investigating an ever-changing landscape of education policy reform (Taylor et al., 1997) that has seen shifts in how education policy and its reform has been considered and understood. Changes in definitions, approaches and theoretical analyses are well-documented and show how thinking has changed in this field as education policy has moved from a local responsibility to a national and global enterprise (Lingard et al., 2016). Ball and Bowe (2020, p. 97) inform us that for the last 40 years, state education systems have been “subjected to incessant and fundamental reform” as governments around the world have navigated new social, economic and technological challenges while also looking to exert more authority in what happens in schools and in schooling.

The field of education policy is a highly contested one, yet the meaning of policy in the everyday education arena is often a taken-for-granted understanding of what policy is. Ozga (2000) stresses that there is no fixed, single definition of policy and how it is understood depends significantly on the perspective of the researcher, policy maker, or educational stakeholder. Some understand policy as it relates to the actions of governments documented in official texts that are handed down to local legislators, school governors, schools, teachers, etc. who are expected to implement these actions for the required educational outcomes. However, Ozga (2000, p. 1, 2) takes a more “diffuse” view of policy. She defines policy as “a process rather than a product, involving negotiation, contestation or struggle between different groups who may lie outside the formal machinery of official policy making ... [policy] is struggled over, not delivered in tablets of stone to a grateful or quiescent population”. Ball et al. (2012, p. 3) take our understanding further to consider policy as a process of enactment. Under Ball, Maguire and Braun’s understanding, policy is taken as “things” (legislation and national strategies) but also “discursive processes that are complexly configured, contextually mediated, and institutionally rendered. Policy is done by and done to teachers; they are actors and subjects, subject to, and objects of, policy”. Both Ozga (2000) and (Ball et al., 2012) show that many studies that focus on how educational policies are disseminated describe ways in which they are implemented, usually from governments to educational institutions in “top-down” or “bottom-up” style models. This is often seen as the way in which educational policy works, with further local support, in a cascading manner, interpreting what is intended by the policy in order for schools and teachers to embrace and integrate the change into their own practice. Yet, in contrast, a different positioning considers policy as a series of enactments; “as dynamic and non-linear aspects of the whole complex that makes up the policy process” (Ball et al., 2012, p. 6) in which stakeholders (teachers, students, senior managers, etc.) act as policy actors who mediate and “produce” policy through interpretation and adaptation within local contexts and settings.

Researchers who work more predominantly in the field of childhood studies and public policy domains conceptualize students as public policy actors and they call for young people to have their views taken into account in policy decisions that affect them directly. They argue that young people need to be afforded greater opportunities to participate in political life at the public level (Arnott, 2008; Hinton et al., 2008). A common underpinning of these calls for greater involvement of children in public policy is their right to participation under article 12 of the UNCRC (see more detail below in Section 3) which asserts children’s right to participate in decisions which affect them directly (United Nations, 2001; see also Lundy, 2007). While the UNCRC has been influential and has driven much research in childhood and participation, the drive for children to be recognized as public policy actors is not only made on a legal basis. As users of public policy, children are affected by reforms to public institutions and policies, and so, it is argued, they should be given the opportunity to participate in decisions regarding change and development (Tisdall, 2008). Underlying this is a shift in perceptions of young people as having the capacity to give valid insights on institutions and services (Arnott, 2008).

In the field of Education as a form of public policy, students are often missing from deliberations on policy reform and how they enact policy through their own interpretations as well as mediating those of their teachers. In this chapter, and the alignment of policy reform, especially in the area of assessment, we take the position that Ozga (2000) and Ball et al. (2012) as well as others, offer us on policy: fluid processes that are contextualized and understood within the environments in which they are situated where students are (and should be) at the heart of policy enactment. Student voice research has shown the value of consultation and participation of students in their own educational development and experience, as well as the improvement of school development activities and the inclusivity of schools that consult all stakeholders about key activities (see Baroutsis et al., 2016; Charteris and Sardon, 2019a, 2019b; Mitra, 2018; Flutter and Rudduck, 2004 for a clear articulation of the workings of student voice work in education). However, students have been less involved in what they themselves call “higher level” policy reforms either in school settings or with governments directly; assessment has been identified as one such “high level” policy arena where students and their voices are absent. More recent research (Elwood, 2012, 2013; Elwood et al., 2017) has taken students as key policy actors in the assessment arena and as such has much to tell policy makers and assessment developers about fair and relevant assessment. It is to this assessment policy reform we now turn.

Assessment policy reform

Isaacs and Lamprianou (2018) remind us that over the last 30 years, governments have increasingly been using assessment policy reforms as mechanisms for improving school outcomes locally, as well as reinforcing their social and economic positions within world-wide settings. National assessment outcomes at both primary and secondary levels and educational policy frameworks that set benchmarks for raising standards in schools are invariably linked to narratives about educating children to face a rapidly changing world as well as improving the economic preparedness of young people as they transition from education to work.

Thus, assessment systems, once a relatively everyday way to gauge children's and young peoples' educational achievements and provide them with educational outcome profiles to make choices about the next stage, have become a major driver for policy makers to influence policy. Most importantly, they have significantly changed pedagogical practice as well as the adaptation of centrally derived curricula in schools.

At local levels across many jurisdictions, we have seen a "take-over" of assessment systems from locally devised programmes, supported by teachers and test development agencies in collaboration and direct communication with schools, to centralized systems of large-scale assessments. These are formally administered at designated key stages, the outcomes of which are used to evaluate not only the students taking these assessments, but teachers, schools and local educational authorities, often to the detriment of schools and their staff if they do not meet set national benchmarks of performance. In the UK, [Baird and Lee-Kelley \(2009\)](#) have described this "take over" of assessment systems and increased government involvement in assessment provision as a significant policy frontline, with assessment policy reform often implemented at speed to enable governments to evidence measurable impacts on education to the electorate within their terms of office. Thus the "role of national assessments can become dominated by a culture of delivery – in particular, the fast delivery of government policies as politicians look for quick wins between elections" ([Isaacs and Lamprianou, 2018; Martens and Jakobi, 2010](#)).

In relation to summative assessments and end of school examinations, there are real risks posed to the reliability and validity of these systems with this culture of fast delivery ([Cadwallader and Tremain, 2013](#)). Limited time frames for development, and lack of piloting and evaluation, allow instability to creep into new systems, often resulting in students and schools left with only post-hoc appeals on final awarded grades when systems do not work as intended. [Cadwallader and Tremain \(2013\)](#) have suggested that many of the problems experienced with more recent assessment policy reform can be understood within the amplified, politicized context of reform programmes and the use of assessment outcomes to fulfill multiple purposes (e.g. individual grades for students, performance measures for teachers and schools). This deliberate and increased use of assessment policy to drive educational change and national assessment systems used to evaluate more things than students, are all activities that have fallen foul of a key fundamental principle with regard to the use (and/or misuse) of assessments and their social impact: "the more any quantitative social indicator is used for social decision making the more likely it will be to distort and corrupt the social processes it is intended to monitor" ([Madaus, 1988](#), p. 89). Once assessment systems become high stakes, even those that might be reasonable monitors of educational success can lose dependability and credibility ([Koretz, 2008](#)).

For years, many assessment researchers have been increasingly concerned with the negative washback that such a reliance on summative assessment has had on the improvement of students' learning and teachers' assessment practice. A global response to this negative washback over recent years has included concerted attempts by educational researchers and practitioners to influence governments away from a reliance on summative assessments and tests and to look to more formative assessment policies to drive change and improve teachers' own assessment practices ([Black and Wiliam, 1998a, 2003; Hopfenbeck and Stobart, 2015](#)). [Florez-Petour \(2015, p. 3\)](#) shows clearly how the policy aspects of formative assessment (colloquially termed *Assessment for Learning*) have been globally imported, piloted, researched and evaluated in a wide variety of contexts; so much so that she suggests that the movement has "the characteristics of a research epidemic". Indeed, many governments have reviewed their national curriculum and associated assessment systems in light of formative assessment developments and looked to the large-scale implementation of assessment for learning programmes to improve learning, teaching and educational standards (see [Hopfenbeck and Stobart, 2015](#) for a special edition on this issue). However, in spite of significant support and almost "evangelical" adoption by practitioners and researchers of the tenets of formative assessment, [Florez-Petour \(2015\)](#) goes on to show that besides its widely recognized positive effects on students and teachers, major questions have seldom been asked about the true efficacy of formative assessment at national levels. She argues that the wide extent of policy borrowing across many contexts that has occurred with frameworks of formative assessment has had minimal impact on the pervasive presence of summative assessment systems. The success of this movement in driving change and improving learning at national levels has at best been "partial" ([Black, 2015, p. 161](#)) with many small-scale interventions successful at the classroom and local levels through increasing the validity of student evaluation but failing to translate into national systems that are robust and reliable, and able to dislodge long established systems of summative assessment.

In broader, more international global perspectives, any consideration of assessment policy and reform need to consider large-scale international assessments and the impact their outcomes can have on nations' policy formation and implementation. At international levels, the rise of the OECD's program for international student assessment (PISA) has had major influence on national governments' assessment policy discussions and directives with direct international policy borrowing becoming ever more prominent as a direct consequence of nations' short comings on PISA tests. [Sellar and Lingard \(2014\)](#) suggest that the OECD has an ever-growing importance and influence in global governance of education through its testing programmes that can direct policy and practice through "soft power", particularly through its unique mechanisms of peer pressure and review. They go on to argue that the "soft power" exerted by the OECD relies on the organizations' leadership drive to both "define the problem" but also to "offer the solution" ([Martens and Jakobi, 2010](#)) through policy evaluation and data generation: "the OECD has therefore gained an important status in several stages of national policy-making, ranging from agenda setting to policy formulation and implementation" ([Martens and Jakobi, 2010, p. 175 in Sellar and Lingard, 2014, p. 929](#)).

With so much continuous policy reform within the assessment arena, there have recently been more concerted efforts from researchers interested in both assessment and students' voices to foreground the importance of listening more systematically to students' experiences as an essential component of understanding the impact of national assessment systems and policies (especially those at school-leaving age) on young people (e.g. [Baird et al., 2011; Banks and Smyth, 2015; Chamberlain, 2012; Daly](#)

et al., 2012; Elwood, 2012; Elwood et al., 2017). Some researchers have started to present the issue of assessment and assessment reform in relation to impact on students as a rights issue (see Elwood and Lundy, 2010); a link that while more obvious now than perhaps in the past, is still rarely made. Thus, there have been calls for students' rights to be taken seriously in light of potential negative washback of large-scale assessment systems, as well as significant power imbalances between test-takers and highly influential global testing organizations (Shohamy, 2001). As the next section of this chapter outlines, the UNCRC designates children as rights holders with rights entitlements, and as such demands that "the best interests of the child" guide decisions regarding public policy actions that affect children and young people directly (Elwood and Lundy, 2010, p. 335). With regard to assessment, Elwood and Lundy (2010) argue that those devising national testing systems should abide by the UNCRC's core principles and take positive action to ensure that young people's views are taken into account in assessment decisions as a matter of course.

Student voices: research and practice

Student voice as a discipline emerged in the early 1990s as educators noted the silence of young people about matters affecting them, at a time when the UNCRC was being widely ratified by countries around the world (see Noyes, 2005; Lundy, 2007). Article 12 of the UNCRC states that "States Parties shall assure to the child who is capable of forming his or her views the right to express those views freely in all matters affecting the child, the views of the child being given due weight in accordance with the age and maturity of the child". In practice, the inclusion of young people's voices in decision making has repositioned student perspectives on teaching and learning more generally (Cook-Sather, 2006), perhaps because "student voice" itself is repositioned as a rights entitlement using the UNCRC, not merely a benevolent idea extended to young people when deemed appropriate by adults. Student voice is widely recognized as a medium for examining the relationship between pedagogy and curriculum (Baroutsis et al., 2016) and as an instrument in assessment for learning (Thomson and Gunter, 2006). Academic and practitioner work has proliferated as early champions of student voice argued for systemic inclusion of students' perspectives in education (see, for example, Fielding, 2001, 2004; Flutter and Ruddock, 2004; Arnot et al., 2004; Cook-Sather, 2002).

Cook-Sather (2006) suggests that the word "voice" arose from the silence of student voices in educational policy and practice. "Student voice" does not indicate simply words spoken by students, however, but includes many ways in which young people express their views and experiences (Robinson and Taylor, 2007). Whilst there is no fixed definition of student voice, its adaptation in a range of contexts and purposes is premised on three convictions: young people have unique perspectives on their education, including teaching and learning; their insights, views and experiences warrant the attention and response of adults; and young people should be afforded opportunities to shape their education (Cook-Sather, 2006). Student voice is thereby founded on students' ability to exert influence in their learning context, to transform learning experiences, and to expand learning (Cook-Sather, 2020).

Proponents of student voice work are amongst the strongest advocates of the need to conceptualize young people as actors rather than the acted upon, or subjects of intervention and assessment (Cook-Sather, 2010). For Cook-Sather (2006), the convictions of rights and respect which underlie student voice demand a rethink of our assumptions about who can and should be an authority on educational practice. Such student voice approaches, however, require a shift in mindset and a sharing of power (Cook-Sather, 2020). Consultation and participation, inherent in student voice practices, are an enactment of redefining the status of young people in education (Ruddock and Fielding, 2006), and article 12 of the UNCRC has played a major part in such changes in mindset because the recognition of children's participation rights demands a transformation of children from the status of passive recipients to respect as active agents with rights entitlements.

Lundy (2007) observes that the implementation of article 12, however, depends on cooperation of adults who may be skeptical about children's capacity to have meaningful input in decision-making, belief that giving children a say will undermine adult authority, and concerns about the time required to comply with article 12. By conceptualizing article 12 in a four-part model: space; voice; audience; and influence, Lundy (2007) addresses some critiques of student voice (see, for example, Robinson and Taylor, 2007) as being tokenistic in some forms by presenting a model of consulting young people in decision-making processes. Yet, Lundy (2018) re-evaluates the criticism of tokenism in child participation, reminding us that tokenism does not justify the stance that it is better not to consult young people at all, than to involve them in a manner that may be tokenistic. Whilst tokenistic consultation with young people may have no impact on decision-making (Tisdall, 2015), Lundy (2018) argues that children also have a right to freedom of expression under article 13 of the UNCRC, regardless of whether these views are given due weight, and States Parties should take measures to respect and fulfill this right.

Discussions and critiques of tokenism in student voice highlight that it is not without its shortcomings. Matters of voice are embedded in structures and relations of power, and student voice is often understood as a challenge to such power structures and relations (Cook-Sather, 2006; Ruddock and Fielding, 2006; Taylor and Robinson, 2009), which can be met with resistance by adults. Fielding (2004) cites Alcoff (1991/1992, p. 12) who asserts that "who is speaking, who is spoken of, and who listens is a result, as well as an act, of political struggle". It is perhaps pertinent to clarify, therefore, that how student voice is defined, what forms it takes, who listens, and how it is interpreted depends in part on the structural context in which this relationship exists (Cook-Sather, 2006). For most students, the opportunity to voice their opinions and experiences rests on the premise of adult educators and policy makers asking them to do so.

The right to have a say, when linked to the right to have that say matter, means that to speak is to have power (Cook-Sather, 2014). Nevertheless, the term "voice" implies a singular, unitary voice but such an assumption is misleading (Robinson and Taylor,

2007); in fact, Arnot and Reay (2004) and Reay (2006) suggest that instead student voice is a cacophony of competing voices. Limitations of some student voice work reflect the tendency by some to perceive the experiences of certain young people as representative of all others (Bragg, 2007; Thomson, 2011). Such assumptions about a homogenous "student voice" deny diversity in students' needs and opinions and serve to occlude the hierarchies of power at work across different student groupings (Cook-Sather, 2006). Any consultation should therefore be reflexively aware of the multiplicity of voices, and the various power disparities that may inhere within and between these groupings as well as in comparison with adults. Student voice, consequently, demands an understanding of equity; what Cook-Sather (2006) argues is founded in rights and respect. Within education, curriculum and pedagogy are the medium and mode of participation for both teachers and students (Lundy and Cook-Sather, 2016), and students' right to express their views freely in matters affecting them, and have them given due weight, is denied if student voices are absent from learning processes, or only allowed in response to adult decisions (Lundy and Cook-Sather, 2016).

Despite this, consideration of children's rights specifically in relation to educational assessment has been neglected (Elwood, 2012; Elwood and Lundy, 2010), and studies within the field of assessment policy formation, qualifications and examination development that have considered students' involvement as critical stakeholders have been more limited in number (Elwood and Lundy, 2010). Indeed, Elwood (2012, p. 499) argues that the qualifications arena seems to be one of the "last bastions of education that has fostered good practice of involving students in policy formation and in consultation around decisions that affect them". Over the years, calls for changes in mind-sets, structures and power relations to support respectful dialogue have emphasized the potential for student voice to enhance understanding of the impacts and effects of educational policies and practices as they are played out (Cook-Sather, 2002; Fielding, 2001). Nonetheless, in some cases, student voice is co-opted into managerial agendas as an imperative of accountability rather than recognition of young people's subjectivity (Fielding, 2001). Indeed, some forms of student voice are contrived through neoliberal perspectives, where young people may be consulted about their learning to raise standards and enhance outcomes for comparative data (Fielding, 2004).

Percy-Smith (2006, p. 172) argues that "the honeymoon period for young people's participation and the celebration of their voices has now passed" and highlights the lack of attention paid to the "wider social, organizational and systemic contexts within which young people participate" – contexts which have become somewhat stark considering assessment decisions during the Covid-19 pandemic. Whilst Bourke and Loveridge (2014, p. 143) argue that "student voice, when used effectively, inherently becomes a pedagogical tool for effective teaching, learning, assessment and social practices within the classroom", evidence of the impact of student voice, and article 12 of the Convention, in the context of assessment continues to be difficult to find (Elwood and Lundy, 2010). Where it has been considered systematically and formally in educational research in assessment reform and student voice, key messages have arisen that are pertinent to the development of assessment systems for fair and just evaluation of student learning. We explore some of these key messages next.

Key messages from research in assessment reform and students' voices

In this section we explore some key messages that have emerged from research which has considered the engagement of students in consultation about their views and experiences of assessment reform. These messages have emerged from studies that were carried out within the jurisdictions of the UK – particularly England, Wales and Northern Ireland (Baird et al., 2011; Barrance and Elwood 2018a, 2018b; Elwood, 2012, 2013a) – as well as the Republic of Ireland (Baird et al. 2015, 2016; Elwood et al., 2017). We consider the key messages collated from these studies about student's experiences of examinations and assessment at major junctures in their education, in "high-stakes" (for them) situations, and in different educational policy contexts. We also present key messages to show the articulation of students' views and perspectives on high-stakes examinations systems about which they are rarely consulted and to offer their perspectives as a contribution to overall discussions about the improvement of assessment policy reform more generally.

In line with Ball et al. (2012) and Cook-Sather (2006) discussed above, students in these studies were considered as social and political agents interacting and mediating assessment policy and practice. These studies set out to change the perception that students do not have something of value to say about assessment reform. The studies collated students' views on the most significant assessment phases of their education, specifically examinations at the end of compulsory schooling (GCSEs and A levels in England, Wales and Northern Ireland for those aged 16 and 18 respectively; Leaving Certificate (LC) in Ireland for students aged 17/18). The authors are aware that there are other studies internationally that have also considered students' views and experiences of assessment (Brown and Hirschfeld, 2008; DeLuca et al., 2018; Hodgson and Spours, 2003, 2005), but the studies referred to in the following sections positioned students deliberately as "social policy actors", significant players in the mediation of national assessment systems not just subjects in their implementation and completion.

As indicated above, students have long been consulted about their learning. In educational practice, consulting with students and having them directly influence their learning and educational experience has been part of school improvement programmes across many jurisdictions and systems (Bourke and Loveridge, 2018). The idea that students should be involved in discussions regarding assessment is not new; it is a central principle of formative assessment, fostering students' engagement and active participation in their learning (Hayward, 2013). However, what is new from this research is the strength of concern from students about their lack of involvement in higher level national decisions regarding changes to key summative assessments that determine their life chances and future opportunities. As we have argued above, the same cannot be said for including students directly within policy making around educational assessment, or national and international assessment systems generally. In this respect, we argue that

students are policy actors, but they are also the “acted upon”, students shape educational assessment policies by their interaction with them within their own contexts but they are also being shaped by assessment policy through assessment opportunities afforded to them and, ultimately, the outcomes they receive.

Student voices on assessment – reform, policy and experiences

From the research studies carried out within UK and Ireland (referenced above), several key themes or messages emerged that allowed a much fuller understanding of the lived experiences of students as they navigate through national assessments and end of compulsory schooling examinations. These messages include students as assessment policy actors, and the importance of listening to young people, to system level issues including equality and ethics. There were similarities between students’ experiences across all the jurisdictions – an interesting point in itself. What these studies show is that students are rarely consulted about what they think about major assessment reform, but when they are, they indicate that assessment is a powerful motivator for them in providing clear indicators of areas of strength and expertise allowing for evidence to support decisions about next steps. However, it can also dominate the final years of their educational careers and create pressure and anxiety generally in their lives that extends well beyond the school gates.

Learning from listening to young people

Assessment and examinations (also referred to in the UK as qualifications) are seen as some of the most important aspects of students’ education, dominating their lives at the end of compulsory schooling but recognized as the educational currency needed for the next phases of their lives post school. A key message from the research studies cited above is the balance between the purpose of assessment policy and exam systems, and over-assessment which impinges on young people’s mental health and detracts from other aspects of their lives as young people. As [Elwood \(2012, 2013a\)](#) and [Elwood et al. \(2017\)](#) indicated, good assessment outcomes are very much linked to aspirations and goals for access to tertiary education, jobs, apprenticeships and whatever comes next, but they also need to be maximized in present day contexts of high competition for jobs and top university places as well as difficult and fluid economic climates, not just locally but throughout the world. Students show clear indications that assessments and, specifically, examinations, were necessary and that they understand the point of such systems, especially in providing fair and commonly understood mechanisms for selection into the next phases of study or employment. The research studies discussed were obviously carried out in those jurisdictions that have a long history of national examinations systems at key stages of education which are also clearly embedded in the culture of education in these countries.

In recent years assessment has been commonly aligned with concerns about students’ well-being and mental health ([Putwain et al., 2015](#)). Under such considerations, there have been calls for national assessments and examinations to be removed in favor of more teacher-based and continuous assessment ([Roome and Soan, 2019](#)). However, for those students who live within systems of high-stakes examinations, not all assessment is damaging or unwanted. In some jurisdictions ([Elwood 2012, 2013](#); [Barrance and Elwood, 2018b](#)) students have indicated that examinations can be a good experience if they are well-prepared and that they can influence learning in affirmative ways, with students being allowed to orchestrate, and take responsibility for, their own success, beyond that decided by their teachers. Such systems of national assessment also provide opportunities for students to evidence dealing successfully with pressurized situations, as well as showing that effort spent in learning and preparing for examination sessions can improve outcomes significantly (and vice versa) ([Baird et al., 2016](#)).

However, assessments and examinations can also be some of the most daunting activities that students have to participate in through their school life. At major crunch points in students’ school careers when examinations and national assessments take place, they can take over all other activities. Moreover, overt (and hidden) messaging from teachers and school leaders about doing well can dominate students’ interactions in schools with negative scenarios of what might transpire if students’ full potentials are not reached through assessment outcomes. Research has also indicated concerns about the amount of testing and assessment that young people encounter in their school careers, with this having increased significantly, especially within post-primary settings, and observation that students do not go for very long within a school year without formal assessments and/or tests. This over assessment has particularly been compounded by those assessment systems that are modular in structure, with students taking a range of formal assessments at fixed times in the year as well as availing of re-sit opportunities ([Pinot de Moira et al., 2020](#)). Indeed, the UK has been criticized in the past for over assessing its school children and having some of the most assessed children in Europe ([House of Commons, 2008](#)). Recent calls for new benchmarks on standards for primary school children in England continue to reflect policies that are outcomes driven ([Weale, 2022](#)).

The over assessment of students in UK schools is a real cause for concern, especially when it starts to interfere with extracurricular activities and comes to dominate what is taught and how it is taught (teaching to the test) in order for schools, rather than students, to be as successful as they can be. The dominating context of assessments and national examinations at particular stages of education for students can limit their extra-curricular activities, impacting on their opportunities to become “rounded individuals” and therefore more attractive to educational institutions looking for “balanced individuals” and “involved citizens” ([Elwood, 2012, p. 505](#)). So, while students see the value of assessments and qualifications, they have shown that often assessment policy reform initiatives do not consider the wider picture of the amount of assessment that can take place when particular models are introduced. Some reforms actually increase the amount of formal assessment that takes place with the rest of students’ school activities suffering as a consequence ([Baird et al., 2011](#)).

Young people as assessment policy actors

Like other educational agendas, assessment reform is no less political. In fact, it is constantly used to drive political agendas (Isaacs and Lamprianou, 2018) and, as we have argued above, not always with children's best interests at the forefront of decision making. There is an important message, therefore, in consulting youth action groups as key assessment policy actors. Often, students see themselves with very little political clout as they do not have the right to vote, and assessment reform, like other reforms, is something that is done to them rather than with them by governments who they may or may not have voted for if enfranchised. Political movements over recent years have called for the lowering of the voting age for young people (Runciman, 2021). Indeed, in the devolved nations of the UK (England, Northern Ireland, Scotland and Wales) there is variation in the articulation of such a move, but there have been changes in the degree to which children are consulted about local-national issues and in them having more of a say in devolved politics. Students' movements across nations are becoming more organized in relation to many school issues, and assessment is high amongst their concerns (see Youth Assemblies in NI, Scotland and Wales for examples). These movements take the form of student parliaments and/or assemblies, students' unions as well as action groups that focus on issues that are of importance to students and determined by them. The COVID-19 pandemic impacted significantly on education systems around the world (Peleg et al., 2021) with subsequent major changes to assessment systems and delivery of end of compulsory school outcomes. Subsequently, more organized student groupings have emerged through and post-pandemic that are engaged more directly with politicians, showing that governments should be interested in students' experiences and should be asking them about major changes envisaged for education in post pandemic societies.

Students in the studies carried out in the UK and Ireland (ibid.) between 2010 and 2017, were clear even then that they should be asked for their views as they are the ones most affected by change, acknowledging that often assessment policy reform is enacted and experienced very differently for different students within localized contexts which also has implications of equality of opportunities afforded to students. Students within their local contexts form learner and assessment identities in relation to how policies are enacted within the local settings of schools: a student is "governed by others and at the same time is governor of him/herself" (Ball, 2015, p. 310). As Elwood (2012, 2013a) has previously argued, this positions students as both national subjects in assessment policy regimes but also as local policy actors, capable of influencing their own lives and the development of their educational identities through localized assessment processes and regulations.

System level issues

A major consideration for students, and key message when asked about policy reform in assessment, is the constant change to systems without consultation with them. Significant assessment reforms, across many jurisdictions are continually made by governments without the deliberate participation of students on stakeholder committees or focus groups that are often established at times of consultation. As discussed above, this is despite governments being under the auspices of Article 12 UNCRC (Lundy, 2007); they are duty bound to consult with young people in all matters that affect them directly in policy directives, and educational assessment should be no exception (Elwood and Lundy, 2010). The main concern about not being consulted about system level changes is that usually the change is brought in "live", i.e., it is changed while students are in the system and often without piloting, so that systems are "tried out" on students, yet it is their grades/results that are affected if the system is flawed. There is often unclear articulations of the ideologies and epistemologies that underpin assessment reform, with students being impacted by the whims of politicians and policy makers to implement their own versions of what they think good assessment should be.

Other key system level factors that students consider as problematic are issues of comparability, with questions about the year-on-year, inter-cohort value of qualifications. Often assessment reform can bring about change for the good, but there are questions to address with various stakeholders about what these new assessments are equivalent to, and how they relate to those that have gone before. Students, who are on the receiving end of taking new qualifications, have argued that there is often no safety-net for them, that they end up with qualifications that are either misunderstood, or not understood as valuable as those qualifications that have gone before because they are new and untested. There is a clear sense that assessment reform can often destabilize well-established assessment systems, because of the desires of politicians to change systems to suit immediate political needs. Students are aware that there are degrees of uncertainty built into new systems, but it is often hard for teachers and students to understand what is expected of new systems, syllabuses and courses, to the extent that policy enactment of new systems at local levels introduces an extra layer of uncertainty and instability that can impact disastrously on students by providing outcomes significantly out of sync with those expected.

Equality (and ethical) implications at the system level

A further important key message that emerges from students is that of fair assessment and equality in policy formation. Equality is a dimension of assessment that has been closely considered within the field, more so perhaps than epistemologies of rights and/or childhood studies (Barrance 2020; Elwood, 2005; Nisbet and Shaw 2020). In the studies that have listened to students' views and experiences, fair assessment was a constant factor raised by students in any considerations for change of systems and/or practices in the assessment arena. Systems of national assessment should encompass different types of assessment techniques so all students can show themselves to good effect. Systems that solely rely on end of courses examinations, it is argued, suit only those students who thrive under pressure or who are good at that type of assessment. Other ways to show learning and competence (such as coursework, practicals, etc.) should always be part of national assessment systems.

Issues around equality are also very closely aligned to issues of ethics and ethical standards in assessment policy reform, yet the ethical implications of what is done to students in the name of reform is rarely studied (Elwood, 2013b; Hamp-Lyons 1997; Oates,

2007; Shohamy, 2001). It is not always clear whether decisions that are made about changes to assessment or the implementation of new assessment systems are considered in the context of whether these decisions bring about good things and in ethical terms, do no harm to those on the receiving end of the changes (Warnock, 1998). Oates (2007) has outlined a range of ethical issues that, he suggests, are associated with assessment policy changes and reform. Of major concern to any system change, he argues, is whether there is misuse of assessment systems for political ends and any significant instability of established systems through mass change with resultant consequences (especially if negative) to the integrity of assessment systems. Key messages from the research with students tended to reinforce those concerns considered by Oates (2007) in that students were aware of the risks involved (to them) of one choice of assessment system and its constituent parts over another, a long side a general lack of a clear rationale, on the part of policy makers shared with students, as to why these choices are made. The adverse consequences of "live" changes to assessment systems becomes another significant source of inequalities in schooling experienced by children and young people, over which they have no control.

Discussion and reflections

This chapter has brought together debates about assessment policy reform and students' voices. Considered separately, they are significant areas of research with their own literatures and underpinning theories. However, these two areas of interest are rarely considered in the same research frame. Yet, as we have shown, assessment is a key aspect of education for young people and their experiences of "doing" assessment and "being" assessed often occur at stages in their educational careers when assessment becomes "most intense and most critical in its impact on lives" (Lumby and Foskett, 2005, p. 89). Listening to students and consulting them on their views about one of the most important aspects of education they encounter has shown to provide insights and perspectives that have much to inform those who are responsible for devising assessment policy as well as those who develop the assessments themselves.

The rise of the student voice movement in education has made the inclusion of students' views in research policy and practice more commonplace (Bourke and Loveridge, 2018), and mainstreamed the acceptance of having students' reflections on their own learning integrated into school level policies, so much so that the possibilities of including student voice in change agendas in school has shown great promise for radical change. Cook-Sather (2002, p. 10) has suggested that through listening to students more systematically and deliberately, "students feel more engaged but are also more inclined to take responsibility for their education [as] it is no longer something being done to them but rather something they do". However, the involvement of children and young people in educational research, policy and practice is so much more complex than some of the work in the field might otherwise suggest. To this end, students across many jurisdictions often indicate that they feel included to a certain degree in shaping certain aspects of their educational experience locally (Bourke and Loveridge, 2018), what (Fleming, 2013) has termed the "private spheres" of institutional decision-making, but feel excluded from higher-level decision making at regional and national levels and assessment policy reform is a prime example of a higher level sphere of decision making from which students feel excluded. As we have indicated, assessment reform can be a "high risk" endeavor, often controversially used to change national systems to advance political agendas. In these high-risk contexts, very little consultation ends up taking place, or is conducted but ignored, to suit political ends. It is in these contexts that students become disempowered in influencing any big decisions and their participation only tolerated in low risk (to adults) domains (Elwood, 2013a) once bigger decisions have been made.

What the research on assessment reform and students' voice evidences is that young people with the capacity to make considered judgements do not automatically opt for what may be perceived as the easiest option. It suggests that many of the arguments made against consulting young people on assessment reform are based on unfair assumptions about what young people will say or the value of their contributions to high-risk policy domains such as assessment systems and their reform. Indeed, Cook-Sather (2006) talks of a "cultural shift" that needs to take place that authenticates the processes of consultation with, and participation of, young people. We are reminded of the need for this "cultural shift" if authentic engagement with students is to succeed in assessment reform. A cultural shift would see the implementation of processes that normalize more informed dialogue between students and policy makers in assessment to realign the balance of power and ultimately challenge, in constructive ways, the sharing of authority about assessment issues (Cook-Sather, 2002; Elwood, 2012).

Elwood (2013a) has argued previously that for direct influence of students' views on assessment reform to become routine, the cultural shift needs to also occur not least within test and assessment development agencies and ministries of education responsible for national assessment systems. This would mean the embedding of consultation with, and participation of, young people within these organizations' decision-making processes as well as their governance structures, to actively support the diverse voices of students' being heard on the range of their activities as well as them being listened to around deliberations on system change and informed of any subsequent actions. The continued absence of student voice in assessment reform either within these organizations or within policy-making domains perpetuates the notion of students being "voiceless" in some of the major educational policy areas that impact on them. Mitchell et al. (1997, p. 853) also talk about the salience of stakeholders, in that they possess "one or more of three relationship attributes: power, legitimacy, and urgency". It would seem that the salience of young people as powerful or legitimate or urgent stakeholders in assessment reform, under Mitchell et al.'s definition, is limited; their voices are not routinely heard or acted upon and their power to influence is restricted. Elwood (2013a) has further suggested that while policy makers continuously reform systems in pursuit of ideological and political agendas, students become "policy victims", suffering all the adverse consequences of unreliable and possibly unethical systems.

In this chapter, we have focused on what Bourke and Loveridge (2018) have called the “promises and possibilities of including student voice in change agendas”. We are convinced that embedding students’ voices in change agendas for assessment reform will ultimately realize better and fairer quality educational provision for all students across ages and stages of schooling, as well as across diverse groups of students. As Elwood (2013a, p. 109) suggests “by authorizing student voice in this area, policy-makers and [assessment] developers must be prepared to share authority about ... assessment matters with students and to rethink who is authoritative about these aspects of educational life”. Only then will students be positioned as consultants within assessment regimes in order that their perspectives can improve our knowledge of fundamental assessment practices and provide for us a fuller understanding of those elements that will promote high quality, fair assessment.

International large-scale assessments (ILSAs) of educational achievement such as the Trends in International Mathematics and Science Study (TIMSS) and the Program for International Student Assessment (PISA) have established themselves as an important part of the educational research and policy landscape. For example, achievement rankings that compare performance of participating countries are fodder for newspaper headlines and are discussed by national, state, and local politicians in most participating countries. The reforms that have been attributed to these studies continue to have a far and lasting reach (Sellar et al., 2017). Reforms directly attributable to PISA in Germany alone included nation-wide education standards and a four-billion euros expansion of all-day schooling, according to the German Federal Ministry of Education and Research. In the past decade, based on PISA results, the Organization for Economic Co-operation and Development (OECD) has strongly advocated for the revamping of the US educational system, arguing that the adoption of the Common Core State Standards will most likely result in increased PISA scores (OECD, 2013; PBS, 2013). More recently, Estonia has embraced educational reforms spurred PISA aspirations, with associated achievement that places this small Baltic country as the new “reference country” in the European Union (Volante and Klingler, 2021).

With steady growth in participation since its inception in 2000, PISA represents the largest ILSA in terms of participating educational systems.¹ For example, 43 educational systems participated in the inaugural PISA cycle in 2000. By contrast, the most recent completed PISA cycle included 85 educational systems in 2022 (see also Sherer and Nilsen, 2023 this encyclopedia). Although PISA is normally on a three year cycle, due to the Covid-19 pandemic, the usual PISA cycle was delayed by one year. Commensurate with PISA’s growth is a marked increase in participant diversity, where differences are due to language, culture, geography, and economic development. For example, Table 1 summarizes the number of PISA participating educational systems, students’ average performance, and the gross domestic product per capita (GDP/capita) in each PISA cycle by OECD members and non-OECD systems, termed *partner* systems. Notable from Table 1 is that among OECD countries, for whom PISA was originally designed, average GDP/capita was US \$38,649 in 2017 (the most recent year reported). This is nearly three times the average of partner systems, who had an average GDP/capita of US \$13,330 in the same year.

Table 1 OECD and partner educational systems that participated in PISA.

OECD countries	2000 ²	2003	2006	2009	2012	2015	2018
Number of participating countries	28	30	30	34	34	35	40
Mathematics score	N/A	499	494	495	494	490	489
Reading score	492	494	489	493	496	493	487
Science score	N/A	N/A	498	501	501	493	489
GDP per capita (USD)	22,880	27,814	37,005	36,900	40,509	37,133	38,649
Partner countries	2000	2003	2006	2009	2012	2015	2018
Number of participating countries	15	11	27	31	31	37	39
Mathematics score	N/A	447	437	437	451	433	431
Reading score	416	440	414	431	448	430	423
Science score	N/A	N/A	429	437	449	439	430
GDP per capita (USD)	10,288	14,138	14,506	14,823	22,233	15,196	13,330

¹Because ILSA participants can be non-national jurisdictions (e.g., cities, areas with contested status like Palestine, and parts of countries like the Flanders region of Belgium), we refer to all participating systems, national and otherwise, as *participants*.

²The original PISA 2000 administration included 27 OECD countries and 5 partner countries. The numbers reflected here include additional countries that took part in a second administration of PISA 2000 in 2001 and 2002.

Such a heterogeneous collection of participating educational systems poses challenges in terms of deciding what should be measured and how to measure it in a comparable way. To that end, carefully developed assessment frameworks for PISA and similar studies (e.g., TIMSS) guide this process. From developing an internationally recognized definition of the content domains (International Association for the Evaluation of Educational Achievement, 2013; OECD, 2017a) to the complex process of instrument translation (OECD, 2014), cross-cultural considerations loom large. But regardless of the care with which a study such as PISA or TIMSS is designed, a cross-cultural measurement paradox exists: “The larger the cross-cultural distance between groups, the more likely cross-cultural differences will be observed, but the more likely these differences may be influenced by uncontrolled variables” (van de Vijver and Matsumoto, 2011, p. 3). In the context of ILSAs, this issue is particularly germane, given recent additions to PISA, which include Cambodia and Guatemala. With an influx of educational systems, ILSA achievement heterogeneity has also increased. In PISA 2000, for example, eight countries scored one standard deviation below the OECD average of 500 ($SD = 100$) in mathematics literacy while in PISA 2018, that number grew to 12 participating systems at least a standard deviation below the historic OECD average (OECD, 2019a). Similar findings are present in TIMSS. For example, in 1995 three countries fell one standard deviation below the TIMSS international average in mathematics at grade eight, compared to six countries in 2019 (Mullis et al., 2020).

The OECD, aware for some time of the widening proficiency levels between participants, has attempted to make various accommodations for lower performing countries. For example, in 2009 the OECD included sets of easy booklets into its design to help better assess lower achieving countries (OECD, 2010). Enthusiasm for this innovation was substantial, with 20 educational systems opting for this option (OECD, 2012). However, as shown in Rutkowski et al. (2018) the approach of including easy booklets did little to improve measurement when compared to administering a common test for all participants. In other words, although the OECD attempted to accommodate for low performing countries the accommodation did not seem to improve measurement for low performers.

To develop an assessment more appropriate for lower performing countries, in 2013 the OECD initiated PISA for Development (PISA-D) with a stated purpose “to make the assessment more accessible and relevant to low-to-middle-income countries” (OECD, 2016, p. 2). Designed as a one-off assessment project resulting in scores comparable to PISA, nine countries are members of the PISA-D project including: Bhutan, Cambodia, Ecuador, Guatemala, Honduras, Panama, Paraguay, Senegal and Zambia. Despite efforts to better align the assessment to what students know and can do in these countries, recent research showed that there remains substantial mismatch between the difficulty of the items on PISA-D and participating students (Rutkowski and Rutkowski, 2021). An example of this discrepancy is represented in Fig. 1. The top panel shows the achievement distributions of the participating PISA-D countries whereas the bottom panel shows the distribution of items in terms of their difficulty. A good examinee-item match would be represented by an achievement distribution which is situated over many of the items. In contrast, Fig. 1 shows that

Fig. 1 PISA-D proficiency distributions contrasted against item difficulty distribution.

for all but the highest achieving country, there is little overlap between achievement distributions and item difficulty. This result implies that in most PISA-D countries, there are few, if any items that measure these populations. A theoretical consequence of this issue is that measurement precision is reduced in these countries (Hambleton and Swaminathan, 1985). In other words, we have less certainty about what these students know and can do. What is not documented in the literature are limits for *accurately* measuring populations that are markedly different from populations for which the test was designed. Understanding whether and to what degree the current models are able to capture achievement in very low performing countries is an important matter since, as noted above, new comers to PISA are characterized by particularly low performance on this assessment.

A brief overview of item response theory

A comprehensive overview of the models and methods used in PISA is well outside the scope of this chapter; however, to orient our conversation we provide a brief overview of item response theory (IRT), which forms the basis of our subsequent analysis. For an introduction to IRT, readers are invited to consult Embretson and Reise (2000) or Hambleton and Swaminathan (1985). In IRT, test items and examinee proficiency occupy the same scale or metric, which is usually assumed to follow a standard normal distribution with mean = 0 and standard deviation = 1. Then, a probability model is used to describe the relationship between items and examinees, where the probability of a correct response to an item j , $P(x_j = 1)$, depends on an examinee i 's proficiency level (θ_i). One equation that describes this relationship is known as a two-parameter logistic (2PL) model (Birnbaum, 1968) and is given as:

$$P(x_j = 1 | \theta_i, a_j, b_j) = \frac{1}{1 + e^{a_j(\theta_i - b_j)}}, \quad (1)$$

where parameters a_j and b_j are characteristics of item j . In particular, a_j indicates the degree to which item j can discriminate among students of different proficiency levels. Higher values indicate that the item discriminates well. The parameter b_j is the item difficulty, which locates item j along the proficiency continuum and can be interpreted as the proficiency value that corresponds to a 50% chance of a correct answer. Higher values indicate a more difficult item and lower values indicate an easier item. The model states that students with higher levels of θ will have a higher probability of correctly answering items. Fig. 2 illustrates a curve, known as an *item response function* (IRF), which graphically represents the model in Eq. (1). This IRF corresponds to an item with a difficulty parameter of 0 and a discrimination parameter of 1. The x-axis represents both item difficulty and examinee proficiency. Here, we can see that as θ increases, the probability of a correct answer also increases.

Implicit in this representation is that test takers, in fact, are measured by items on the assessment. In other words, on a given assessment, test takers should have some probability of a correct answer on many of the items. Unfortunately, however, this is not the case for the lowest performers. As Rutkowski and Rutkowski (2021) show the probability of a correct response on a typical PISA-D item is just 0.11 for an average student and just 0.06 for lower performers in Zambia. Importantly, for a multiple choice item with the standard four response options, these probabilities are well below chance.

Fig. 2 Item response function for $b = 0$, $a = 1$.

Extreme proficiency distributions

To understand whether the models used in ILSAs like PISA are able to accurately measure extreme proficiency distributions such as those observed in recent cycles of PISA and PISA-D, we conducted a Monte Carlo simulation study. Although our primary interest is on low performers, we also incorporated in our design a population of high performers. As the basis for our simulation, we considered an extreme proficiency mean to be well outside of what has been historically observed in PISA (or PISA-D). In mathematics, Zambia was the lowest performing country in PISA-D with an average score of 258 (OECD, 2018). As an aside, this score also suggests that a typical Zambian student is measured by a single math item. Given that this score is about 2.5 standard deviations below the historic PISA mean of 500 ($SD = 100$), we selected as our extreme achievement distributions the equivalent of 200 and 800. On an IRT scale, which typically uses a standard normal distribution, this translates to the lowest and highest populations having achievement distributions of $N(-3, 1)$ and $N(3, 1)$, respectively. To represent a typically performing population, we also simulated a population of examinees with an achievement distribution of $N(0, 1)$. This implies mean proficiency differences of six standard deviations, with the extreme groups located three standard deviations above or below the middle group. By comparison, in PISA 2018, the lowest achiever, the Dominican Republic, had a mean in science of 336. The highest achiever, the participating regions in China, achieved a mean of 590. Given a historic standard deviation of 100, this suggests a span of 2.54 standard deviations. To that end, our simulation represents an extreme case in terms of cross-country achievement differences.

For our simulation, we used PISA 2015 science item parameters (OECD, 2017b). Although there are both dichotomous (right/wrong) and polytomous (partial credit) items in PISA, we simplified our simulation design and treated all parameters as though they resulted from dichotomous items, by eliminating the additional step parameters associated with a polytomous item. To mimic the PISA design (Rutkowski et al., 2014), we assigned items to 12 blocks of non-overlapping items, which were assembled into 36

Table 2 Simulated incomplete block design.

Form	Item block											
	1	2	3	4	5	6	7	8	9	10	11	12
1	X						X					
2	X									X		
3		X						X				
4			X						X			
5			X									X
6				X			X					
7				X						X		
8					X						X	
9						X						X
10						X	X					
11	X							X				
12					X			X				
13		X							X			
14						X			X			
15			X							X		
16		X									X	
17				X							X	
18					X							X
19							X	X				
20							X		X			
21							X				X	
22								X		X		
23								X				X
24								X	X			
25									X		X	
26							X			X		
27									X	X		
28										X		X
29								X			X	
30									X	X		
31							X					X
32									X			X
33											X	X
34		X		X								
35	X				X							
36			X			X						

different forms. This design included two blocks of items per form. For example, form 1 featured block 1 and 7; form 2 featured block 1 and 10. This design ensured that forms were linked and that each simulated examinee responded to as many as 35 items. Our simulated assessment design is represented in Table 2, where “X” indicates that a block of items occurs in a form.

From the previously specified population proficiency distributions, we sampled 5000 examinees for each group, giving a total sample size of 15,000. Test forms were randomly assigned to examinees and simulated responses were recorded. The simulation and item response routing was completed in R (R Core Team, 2021) using the *lsasim* package (Matta et al., 2018). We then treated item parameters as fixed values in a latent regression model where the group served as a covariate in the model (Mislevy et al., 1992; von Davier and Sinharay, 2014). Using the group with a mean of zero as the reference group, the resulting regression coefficients represent the estimated achievement means for the other two groups. Population achievement distributions were estimated using the TAM package (Robitzsch et al., 2017). We repeated this process 500 times to achieve a stable solution.

The results of the simulation produced achievement means of -3.006 ($SD = 0.0096$) and 3.007 ($SD = 0.0087$) for the low and high performing groups, respectively. This result is essentially perfect recovery of the generating population proficiency values. To give some context to these results, Fig. 3 shows the distribution of item difficulty for these items, with the bulk centered around a difficulty value of zero.

To further contextualize the results, we calculated the probability of a correct response for a *typical* examinee in the low group—one who has a proficiency value of -3 . On the easiest item (difficulty value $= -2.403$), the probability of a correct response was calculated as 0.15. The probability fell markedly for an item of typical difficulty (difficulty value $= 0.054$) and was calculated as 0.0005. Finally, the most difficult item (difficulty value $= 3.327$) produced a probability of correct response equal to 0.0001, or nearly a 1 in 10,000 chance of a correct answer. Notably, these probabilities are for a middle performing examinee in this group—half will have slightly higher or lower probabilities, depending on their proficiency value. Nevertheless, for most of the examinees in the low group (and to a large extent the high group), most are measured by few or no items. Recall, too, that the assessment design was such that each examinee took just 2 of 12 possible blocks of items, meaning that the likelihood of being measured by no items for a given examinee in either of these groups was high.

Despite poor or non-existent measurement for groups at the extreme ends of the proficiency distribution, the estimation method recovered accurately the underlying proficiency distributions. To our thinking, this points to a strange phenomenon that requires serious attention. The statistical machinery used to estimate population-level achievement distributions can locate a group on the achievement continuum, regardless of how poorly that group is measured. Taking a mechanical perspective on this, the response vectors for the low achieving population are mostly zeros overall and, for many individual examinees, there will be response vectors that are entirely zero. This suggests that we learn *nothing* about what these students know and can do. We only know that they don’t know the material on the assessment.

Discussion

Historically, the OECD developed PISA for economically developed, industrialized member countries. Indeed, the very first group of PISA participants included 28 OECD members and just four partners. In the second round of PISA 2000, conducted several months later, the lowest performer was Peru, a low-income country at that time. Indeed, early PISA documentation and procedures reflected the OECD orientation. For example, the 2000 framework was explicit in that the instruments should reflect OECD member country educational and cultural contexts and the target age of 15 was selected as one where most OECD students were still in compulsory education (OECD, 1999). Further, until the 2015 cycle, the methods used to estimate item parameters used information *only* from OECD countries completely omitting partner countries (OECD, 2014). Only recently was a plan developed to allow partner countries to attain an “associate” membership tier that would allow for full voting rights (Schneider, 2019); however, in 2018 most partner countries still held “observer” status (OECD, 2020) with no right to vote on design, implementation, or other

Fig. 3 Item difficulty distribution.

PISA matters. Currently, the expert groups that are responsible for overseeing the development and technical implementation of PISA are heavily represented by researchers, civil servants, and contractors from OECD member countries (OECD, 2020). PISA architects are aware of the privileged position of OECD countries and the possible disadvantage that this confers on partner countries. To that end, the OECD has embraced efforts to more inclusively involve all participants in the process. Nevertheless, the evolution is slow and vestiges of the OECD-centered perspective remain.

In the realm of PISA innovation, practicalities also prevail. For example, the PISA for Development assessment contained no new material to measure participating countries. Rather, the assessment comprised previous PISA content, supplemented with existing material from other international assessments (OECD, 2019c). To that end, the main survey contained 50–60% of trend items from PISA 2015, with the remainder of material drawn from existing surveys (2019b). Although about 60% of the item pool measured the two lowest of eight achievement levels in PISA, previous research showed that most students were poorly measured or not measured at all by PISA-D (D. Rutkowski and Rutkowski, 2021). Nevertheless, our simulation showed that, from a modeling perspective, the statistical machinery used to estimate achievement in PISA and other ILSAs is able to recover the true underlying proficiency distributions for even a very extreme populations.

In our simple simulation we found that current models and methods assure statistical validity on PISA and related ILSAs in that few, if any, test questions need to measure participants to get an accurate estimate of aggregated achievement distributions. Nevertheless, we believe that the statistical results should be decoupled from the validity conversation around our findings. Although it is possible to locate an educational system along an achievement continuum, regardless of the extent to which participants are measured, we are not reasonably able to say what this population knows and can do in a given domain. We return to PISA-D for another example: in Cambodia, Guatemala, Honduras, Paraguay, and Senegal, median math achievement was at level 1b. Students at this level of achievement can follow instructions in simple text and can sometimes perform the first step of a two-step math problem (OECD, 2018). Importantly, just 11 items on the math portion of PISA-D measure at this level or below. Zambia's median math achievement was at level 1c, which is measured by only two items. Students at this level can follow a single, clearly prescribed instruction and perform a single step, such as reading a single value from a chart or table. We can hardly argue that educational outcomes are poor in PISA-D countries given that most participants are below minimum levels of competency. Yet we clearly are not tapping into the knowledge and skills in these populations by measuring with so few items. The reading domain on PISA-D was far better targeted to the tested populations. This portion included a domain called *reading components*, which includes sub-skills or building blocks of reading literacy. A substantial portion of the PISA-D reading items came from the reading components domain 88 of 154 total items and 75% of students received a cluster of reading component items. Importantly, nearly all of these items were located at level 1a or lower, allowing for better measurement at the lower end of the achievement continuum (OECD, 2019c).

With expanding participation in international assessments, where should testing organizations go from here? We highlight several possibilities, which are currently in various stages of implementation. First, computerized assessment platforms offer a promising solution to many of the issues outlined in the current manuscript. Improvements are offered by way of adaptive testing, which allows for an assessment to better target the achievement levels of participants. PISA 2018 introduced an adaptive design to the reading domain and PISA 2022 will introduce an adaptive design in math. Although the OECD plans to develop items to enhance measurement at the low end of the continuum for 2021 (now 2022, due to the pandemic), this innovation is only planned for the computer-based version of PISA (OECD, 2019b). Unfortunately, many of the lowest performing countries are expected to participate in the paper-and-pencil platform, meaning that these countries will not be able to take advantage of specially designed items. Nevertheless, countries have an option to take part in what is effectively a continuation of PISA-D, administered via paper-and-pencil in parallel with the computer-based version of the assessment, in which most countries are encouraged to participate. A second possibility, should the OECD continue to offer this PISA-D option, would be to include content that is analogous to reading components for math and science. The IEA has recently implemented a design feature called a “group adaptive design” where booklets of easier or more difficult items are distributed in varying proportions across countries, depending on observed or expected achievement (Mullis and Martin, 2019). The results of this innovation are not yet published; however, this might also offer an opportunity for improving measurement in extreme populations.

Given the promise of computer-based testing, we conclude with a call for testing organizations such as the OECD and IEA to move toward universal computer-based testing. Of course, this is no small feat. Available resources limit computer availability in less economically developed countries and some middle-income countries refuse the move to a computerized platform. Providing necessary technology during the assessment window could be done by aid organizations or charitable foundations. And gently but firmly compelling technological holdouts is a delicate but important task that should be taken up by organizational leadership.

Purpose

Assessment in education—as it is practised within schools and colleges all over the world—is so commonplace, so deeply embedded, and often so ritualized, that it is easy to take it for granted. Indeed, sometimes an assessment can become so embedded and so ritualized that the reason for its very existence becomes obscured. Unfortunately, when we fail to pay sufficient attention to the purpose, or purposes, that an educational assessment is supposed to be serving, bad things can happen. The present chapter concerns the very many different purposes that drive assessment in education, and explains why they need to be carefully taken into account whenever an educational assessment is designed, used or evaluated.

Listing purposes

Examinations are used for many purposes, and many of the difficulties and evils connected with their use arise from the attempt of those who frame the Examinations, either to effect too many things by one instrument; as, for instance, to pick out the most proficient, to reject the dunces, and to give an impetus to a certain kind of study all by the same series of papers; or from their not having a clear view of what they are aiming at.

Latham (1886, p. 2).

Although much has been written about the purposes of educational assessments, there is no cohesive literature on the topic, in the sense of an established body of accumulated wisdom. Instead, the corpus of work on purposes, such as it is, tends to be fragmented, with little in the way of cross-referencing. Many of the interesting papers that I have read on assessment purposes I have merely stumbled across. This makes the topic quite hard to review!

Papers on assessment purposes often feature a particular construction—the “long list”—which helps to illustrate the fact that there are a surprising number of them, while also suggesting (in line with Latham) that problems can arise when the same assessment is used to achieve too many different purposes. The earliest “long list” that I have discovered comes from a paper entitled *Preliminary Steps in Initiating a Testing Program*. In it, [Stevenson \(1922\)](#) identified 26 purposes, which he described as merely a “partial list of uses for standardized tests” (p. 156). The list began:

1. For diagnosing common and individual errors as a basis for remedial instruction.

2. For prognosis of pupils’ abilities.

3. For classification of pupils according to ability.

4. To determine whether sufficient time is being spent on a given subject.

Stevenson (1922, p. 156).

To cut to the chase, the list ended:

23. As a means of interesting children in school work and improvement. (Especially is this true if charts or graphic records of their own work are kept.)

24. As a protection to the teacher or principal from the irate parents. (Parents who are not satisfied with the teacher's marks may be shown definitely how their child stands in relation to the other children of the room.)

25. To show the relative standing of different grades or buildings within a system or a comparison of these with other cities.

26. To show where emphasis on different subjects should be placed.

Stevenson (1922, p. 156).

Lists of purposes—some shorter, some longer—are a feature of many of the papers that I have stumbled across over the years, including:

- Odell (1928)—15 purposes of “measurements”
- Tyler (1942)—6 purposes of “evaluation”
- Hieronymus (1972)—10 purposes of reading assessment “instruments”
- Shepard (1979)—7 purposes of “assessment and evaluation”
- Haladyna et al. (1991)—29 uses of “standardized test information”
- Baker (2000)—10 purposes of “tests”
- Mansell (2007)—20 uses to which “test and exam results” contribute
- Cedefop (2010)—40 purposes and functions of “qualifications”

Having prepared a few long lists myself (e.g., Newton, 2007a,b), I can vouch for their sobering rhetorical force. They are very useful tool for helping stakeholders to appreciate why an assessment that has been designed to be used for one particular purpose may not necessarily be equally suitable to be used for a quite different one.

Analyzing purposes

One of the easiest mistakes to make, when considering what the purpose of an educational assessment might be, is to foreclose analysis too soon, typically by remaining purely at the *measurement level*. In other words, it is tempting to assume that the fundamental purpose of any educational assessment is to measure. (I use this term in a fairly liberal, encompassing sense, allowing it to be interpreted: either strongly or weakly; literally or metaphorically; macroscopically or microscopically.) If so, then all that really needs to be established is the domain of learning that needs to be measured, and the approach that will be taken to measuring it.

Imagine, for instance, an assessment that a teacher had decided to administer, following a year of teaching maths to a class of 13-year-olds. If we were to ask her what her purpose was, in administering the assessment, she might reply (matter-of-factly) that it was simply to measure how much maths each of her students had learned that year, which is why she had designed a test to sample all of the content that had been taught. This would represent a simple measurement-level analysis.

As it happens, even this response would require a little more unpacking. In particular, did the teacher specifically want to measure how much maths each student had learned *that year*? If so, then this would actually require a progress calculation of some sort—to compute the difference between each learner's level of attainment at the beginning of the year and their level of attainment at the end of the year—which might require two separate tests, both of which would need to cover all of the content of that year's course, or perhaps just the same test administered twice. Alternatively, was the teacher simply interested to know how much mathematical knowledge and skill each student had acquired *by the end of her course of instruction*? In that case, a single,

end-of-year maths test might suffice. On the other hand, that test might need to cover more than just the content that she had taught, *that year*, perhaps also including content that had been taught in previous years. This would mean measuring students in terms of a broader attainment domain, related to progression across the school curriculum for maths.

In fact, to fully understand why this teacher felt the need to administer an end-of-year test, we would need to extend our analysis beyond the measurement level, to the *decision level*. The primary question, here, is what she actually intended to *do* with the information that the test would provide, i.e., the information captured by the test result. The bottom line is that we assess in order to generate information, and that information will subsequently be used to make a decision (generally speaking).

It is important to understand this, because different kinds of decision-making may require access to different kinds of information, which may require different kinds of assessment evidence. In other words, in order to know how to design any particular educational assessment, we will need to work backwards from the decision that ultimately needs to be made, and the kind of information that would be needed in order to make it.

Imagine, now, that our maths teacher had wanted to decide which of her students was the most deserving of a reward for having worked hard that year. If so, then she might conclude that this purpose could best be served by measuring progress in attainment in maths; defined purely in relation to the content of the course that she had taught that year. This would enable her to identify the most deserving student in terms of the magnitude of the difference between their level of attainment at the beginning of the year (based on one test) and their level of attainment at the end of the year (based on a second version of the same test).

If, instead, she wanted to make a quite different kind of decision—for example, to decide which of her students had the most potential to benefit from studying an optional advanced level maths course in the following year—then she might conclude that she needed to measure a quite different aspect of attainment. This might require just a single, end-of-course test of overall level of attainment in maths; this time defined relative to the broader school curriculum, and perhaps extending to content that had not yet been taught.

Differentiating between purposes

Results from educational assessments are used for all sorts of purposes, to make all sorts of decisions. This is a long list that I prepared for the last edition of this encyclopedia (Newton, 2010):

1. To decide whether individual students are making sufficient progress in attainment in relation to expectations or targets; and, potentially, to allocate rewards or sanctions (student monitoring)
2. To identify students' proximal learning needs, to guide subsequent teaching interventions (formative)
3. To judge the social or personal value of students' achievements (social evaluation)
4. To clarify the type and extent of students' learning difficulties, or needs, in light of well-established criteria (diagnosis)
5. To determine whether students meet eligibility criteria for special educational provision (provision eligibility)
6. To identify students who differ significantly from their peers, for further assessment (screening)
7. To segregate students into homogeneous groups, on the basis of aptitudes or attainments, to make the instructional process more straightforward (segregation)
8. To identify the most suitable courses, or vocations for students to pursue, given their aptitudes (guidance)
9. To identify the general educational needs of students who transfer to new schools (transfer)
10. To locate students with respect to their position in a specified learning sequence, to identify the level of course which most closely reflects it (placement)
11. To decide whether students are sufficiently qualified for a job, course, or role in life—that is, whether they are equipped to succeed in it—and whether to enroll them or to appoint them to it (qualification)
12. To predict which students—all of whom might, in principle, be sufficiently qualified—will be the most successful in a job, course, or role in life, and to select between them (selection)
13. To provide legal evidence—the license—of minimum competence to practice a specialist activity, to warrant stakeholder trust in the practitioner (licensing)
14. To provide evidence—the certificate—of higher competence to practice a specialist activity, or subset thereof, to warrant stakeholder trust in the practitioner (certification)
15. To identify the most desirable school for a child to attend (school choice)
16. To decide whether institutional performance—relating to individual teachers, classes or schools—is rising or falling in relation to expectations or targets; and, potentially, to allocate rewards or sanctions (institution monitoring)
17. To identify institutional needs and, consequently, to allocate resources (resource allocation)
18. To identify institutional failure and, consequently, to justify intervention (organizational intervention)
19. To evaluate the success of educational programs or initiatives, nationally or locally (program evaluation)
20. To decide whether system performance—relating to individual regions or the nation—is rising or falling in relation to expectations or targets; and, potentially, to allocate rewards or sanctions (system monitoring)
21. To guide decisions on comparability of examination standards for later assessments on the basis of cohort performance in earlier ones (comparability)
22. To “quality adjust” education output indicators (national accounting).

This is not an exhaustive list, but it does help to illustrate the many different kinds of decision that can be based upon educational assessment results. Again, the important point is that different kinds of information may be required to make different kinds of decision, which may necessitate quite different assessment design choices. Thus, [Millman and Greene \(1989\)](#) illustrated how assessments designed for program evaluation might differ from those designed for other purposes, such as student monitoring; by targeting learning objectives beyond those specific to the course; by employing item formats unfamiliar to those following the course; by allocating different items to different students, to sample learning objectives thoroughly; and by scoring by learning objective, rather than at an overall level. This kind of assessment would not even report at the level of individual students, let alone allow a user to monitor student progress in relation to a specific course of instruction.

Similarly, the assessment evidence required to decide whether a student is progressing at a suitable rate in chemistry (student monitoring) will be quite different from the assessment evidence required to identify their day-to-day learning needs in chemistry (formative). The former is likely to involve a high-level inference, concerning the student's overall level of attainment; whereas the latter is likely to involve many low-level inferences, concerning the nature of the student's knowledge or skill, in relation to specific concepts or practices. Clearly, evidence that is only elicited at a high level, for the purpose of monitoring, cannot subsequently be used to draw low-level formative inferences. And, although it might be possible, in theory, to re-use evidence elicited at a low level (for formative purposes) to draw high-level inferences (for monitoring, selection, or suchlike) it is a moot point as to whether this is really viable, in practice.

The purpose of this section is to reinforce the key message of this chapter: there are many different purposes for which educational assessments are designed; and an assessment designed to serve one purpose cannot necessarily be used effectively to serve others.

Differentiating within purposes

The list of 22 presented above is best understood, not as a list of discrete purposes, but as a list of categories of purpose. Within each of these categories, it would be possible to identify distinct sub-purposes; and these distinct sub-purposes—even within a single purpose category—might implicate quite different kinds of decision, which might require quite different kinds of information, which might necessitate quite different assessment design choices. Again, program evaluation provides a good case in point. As Cronbach explained many decades ago:

If you wish only to know how well a curriculum is achieving its objectives, you fit the test to the curriculum; but if you wish to know how well the curriculum is serving the national interest, you measure all the outcomes that might be worth striving for.

[Cronbach \(1964, p. 243\).](#)

Similar distinctions could be made in relation to many other categories of purpose, where different sub-purposes are associated with different inferences. This explains why [Nitko \(1989\)](#) was able to identify five different categories of diagnostic test, each requiring a different approach to test design. It also explains why tests used for system monitoring are often designed very differently from one country to the next; for example, New Zealand's National Education Monitoring Project versus the USA's National Assessment of Educational Progress (see [Newton, 2008](#)). In New Zealand, the NEMP was intended to be of particular use to teachers and curriculum designers; and, consequently, it was designed to report at the level of individual tasks and small clusters of tasks. In the USA, although originally reporting at the level of individual tasks, the long-term trend NAEP was specifically redesigned to be of use to policy makers and stakeholders, subsequently reporting only at the overall subject level.

Even the distinction between high stakes and low stakes decision-making will necessitate different design choices. Assessments that have high stakes for individuals—such as qualification, selection or licensing—will need to be designed with high levels of security in mind, at all stages of the assessment lifecycle, e.g., from identity checking at a test center, to the disposal of completed test scripts ([Millman and Greene, 1989](#); [Schmeiser and Welch, 2006](#)). Such considerations simply do not arise when results are used only for low stakes purposes, where cheating does not present a significant threat to validity.

Classifying purposes

It is fairly easy to develop schemes for classifying assessment purposes. For instance, those up to purpose 14 (above) relate primarily to individuals and are based upon individual results; whereas those from 15 to 22 relate to larger entities (such as schools, cohorts or nations) and are based upon aggregated results. Equally, though, the same 22 categories of purposes could be classified in an entirely different manner, as illustrated by the following scheme:

1. Personal decisions, made by students and parents (e.g., social evaluation, guidance, school choice)
2. Educational decisions, made by teachers and psychologists (e.g., formative, diagnosis, screening, placement, transfer, segregation)
3. Administrative decisions, made by gatekeepers (e.g., provision eligibility, qualification, selection)

4. Managerial decisions, made by those supervising and directing performance (e.g., student monitoring, institution monitoring, system monitoring, resource allocation, organizational intervention)
5. Endorsed decisions, made by consumers (e.g., licensing, certification)
6. Technical decisions, made by technicians and analysts (e.g., comparability, national accounting)
7. Evaluative decisions, made by researchers (e.g., program evaluation).

Scholars who write about assessment purposes often introduce a new classification scheme to the literature (e.g., [Odell, 1928](#); [Cook, 1951](#); [Findley, 1963](#); [Bloom et al., 1971](#); [Millman and Greene, 1989](#); [Nitko, 1989](#); [Hopkins et al., 1990](#); [Mehrens and Lehmann, 1991](#); [Black, 1998](#); [Pellegrino et al., 2001](#); [Schmeiser and Welch, 2006](#); [Gronlund, 2006](#); [Nitko and Brookhart, 2007](#); [Thorndike and Thorndike-Christ, 2010](#); [Baker, 2013](#); [Haertel, 2013a](#)). This observation, in itself, would seem to cast some doubt over the utility of the exercise. In an ideal world, a classification scheme might help the reader to understand how certain kinds of purpose are associated with certain forms of assessment. But the reality is simply not that straightforward, and the many classification schemes in existence seem to provide little more than relatively arbitrary and contestable groupings which lack obvious utility.

Both [Millman and Greene \(1989\)](#) and [Schmeiser and Welch \(2006\)](#) have noted the lack of a universally accepted scheme, with the implication that it would be useful to have one. Yet, classification schemes are not necessarily always a good thing. Questionable classifications can mislead policy makers, users and members of the public into drawing inappropriate inferences, by implying that sub-purposes within each category or class are fundamentally equivalent, in a functional sense. This can mislead stakeholders into assuming that similarly grouped purposes can straightforwardly be supported by the same assessment instrument. Conversely, emphasizing differences between, and even within, purposes helps to foreground the absolute necessity of tailoring assessment design to a precise statement of intended purpose(s). This is another reason to recommend the long list, which resists further classification.

Purposes and validity

Validity is about assessing the right thing in the right way to produce accurate and useful assessment results ([Newton, 2017a](#)). Expressed like this, it is clear that validity and purpose are intimately entwined, which is evident in the definition of validity that appears in the most recent (sixth) edition of the North American *Standards for Educational and Psychological Testing*:

Validity refers to the degree to which evidence and theory support the interpretations of test scores for proposed uses of tests.

[AERA, et al. \(2014, p. 11\)](#).

The precise formulation of this definition—in terms of interpretations for uses—is significant. It states that validity concerns the suitability of information provided by assessment results for the use to which it will be put, i.e., the decision that needs to be taken. Although this interpretation-for-use formulation has only featured in the last two editions of the *Standards*, its fundamentally pragmatic approach, which links validity directly to purpose, has been evident since the very first edition.

Ironically, this important principle that validity can only be judged in relation to purpose—more specifically, the way in which this principle was presented in the first few editions of the *Standards*—seems to have been responsible for entrenching what is now generally accepted to be a particularly unhelpful construction of validity. This is the idea that there are distinct kinds of validity, including content validity, criterion validity, and construct validity ([Newton and Shaw, 2013](#)).

Table 1 is adapted from [Anastasi \(1976\)](#), who was attempting to illustrate the validation of a single arithmetic test in relation to multiple purposes. The idea that she was trying to illustrate is that different ways of interpreting test results (in terms of different kinds of attributes) may suggest different approaches to validation. Thus, a test of achievement (i.e., attainment) will tend to be validated logically, by analyzing its content; whereas a test of aptitude will tend to be validated empirically, by correlating its outcomes against a future criterion measure. Back in the 1960s and 1970s, the former tended to be described as establishing content validity, and the latter tended to be described as establishing criterion validity.

Table 1 Using a single test for multiple purposes.

Testing purpose	Illustrative question	Validity type
Test of achievement in elementary school arithmetic	How much basic arithmetic has Jo learned?	Content
Test of aptitude for high school maths	How effectively will Jan learn higher maths (in the future)?	Criterion
Test of logical reasoning	How intellectually gifted is Jean?	Construct

Adaptation of Table 13, from [Anastasi \(1976, p. 158\)](#).

Unfortunately, this over-simplified characterization of validity theory and validation practice became increasingly associated with inadequate validation research, and unjustified validity conclusions (see [Newton and Shaw, 2014](#)). Scholars including [Messick \(1980\)](#) and [Guion \(1980\)](#) argued forcefully against what they described as a “trinitarian doctrine” of validity—which distinguished three different kinds of validity—and argued instead that all validity ought to be conceptualized as construct validity. In turn, construct validation ought to be conceptualized as a scientific program of research, requiring the integration of evidence and analysis from a variety of logical and empirical techniques. This proposal to unify validity theory and validation practice was welcomed, and is now generally accepted.

This shift toward a unified conception of validity does nothing to undermine the link between validity and purpose. However, the link tends now to be framed in terms of different interpretations for different uses, rather than in terms of different kinds of validity. Notice that the point of column 1 of Anastasi’s table was also to foreground the different interpretations that needed to be validated, in relation to different uses. So, the underlying principle of relating validity to use (i.e., decision-making) has remained the same. (Although Anastasi labeled column 1 “testing purpose” these purposes were actually left implicit, while the interpretations were foregrounded.)

The logic of validation, implicit in Anastasi’s table, would go like this. First of all, results from the arithmetic test would need to be validated as measures of achievement in elementary school arithmetic. Of course, as the test was specifically designed to measure this attribute, we might expect the validation program to be able to establish that it had a high degree of validity, in relation to this interpretation of results, and therefore in relation to uses premised upon an interpretation of this sort. Subsequently, if results from the same arithmetic test were to be interpreted in terms of a more general aptitude for mathematics, for a different kind of decision-making, then that would require additional validation research. This might include evidence of the degree to which structurally similar elementary school arithmetic tests (administered in the past) had been able to predict subsequent achievement in high school maths. Naturally, though, as these elementary school tests were designed to measure arithmetic, rather than aptitude, *per se*, we might expect a somewhat lower degree of validity in relation to this interpretation (and use) of results. The same would be true for an interpretation of results in terms of logical reasoning ability; for which we might expect an even lower degree of validity.

The key insight from this pragmatic approach to validity and validation is that, it is not *the test* that is validated, but plausible *interpretations* of results from the test, and therefore the *uses* that are premised upon such interpretations. Consequently, different interpretations (and uses) of results from a single test may be judged to have different degrees of validity. Although, in recent years, there has been a renewed emphasis upon interpretations within validity theory, this is certainly not a new way of thinking. The link between validity and purpose has been recognized for as long as validity has been theorized, for instance:

If a test is “valid,” it is valid for a *given purpose*, with a given group of pupils, and it is valid only to the degree that it accomplishes that specific purpose for that specific group. It is meaningless to speak of any given test as being valid or invalid apart from any consideration of the purpose it is intended to serve or of the group to which it is to be given. [...] If a test is to be made most valid for one purpose, its validity for other purposes must often be sacrificed. An “all-purpose” test can perform none of its many purposes effectively.

[Lindquist \(1936, pp. 21–22\).](#)

Purposes and evaluation

The pragmatic approach to conceptualizing validity has remained popular since validity was introduced to the educational measurement lexicon during the 1920s ([Newton and Shaw, 2014](#)). More recently, though, [Messick’s \(1989\)](#) argument in favor of a unitary conception of validity—which focused a great deal of attention upon interpretations, uses, meanings, and consequences—initiated what has become known as the Great Validity Debate ([Crocker, 1997](#)), which rumbles on to the present day ([Newton and Baird, 2016](#)). As this debate developed, the pragmatic approach was challenged from opposing directions.

From one direction, it was argued that the pragmatic approach to defining validity—in terms of interpretations, and especially in terms of uses—is too broad. Instead, validity should be defined more scientifically, by focusing purely upon the capacity of a test to measure. This should exclude the evaluation of test use, which is an unnecessary distraction from proper validation ([Scriven, 2002](#); [Borsboom et al., 2004](#)). However, from precisely the opposite direction, it was argued that the pragmatic approach to defining validity is too narrow. Instead, validity should be defined more ethically, by extending its focus to include even unintended consequences from testing. This should emphasize the evaluation of test impact, which is a necessary component of validation ([Linn, 1997](#); [Moss, 1998](#)). The key features of these three approaches are summarized in [Table 2](#); the first row illustrates the intended focus of validation research; the second row illustrates the ultimate validation question.

It is not possible to identify a logically correct answer to the question concerning how the word “validity” ought to be defined ([Newton and Shaw, 2016](#)). This is really a consequential matter, which turns on the consequences of defining validity one way rather than any other. Although this is a challenging, and an as-yet-unresolved debate, it has been really useful in illustrating, and emphasizing, the many different facets of assessment policy and practice that need to be evaluated, whether under the banner of validity, or not.

Table 2 Alternative approaches to defining validity.

<i>Essentially scientific approach</i>	<i>Fundamentally pragmatic approach</i>	<i>Ultimately ethical approach</i>
Technical quality of measurement.	Technical quality of measurement (for specified purposes). Practical utility of measurement-based decisions (for specified purposes).	Technical quality of measurement (for specified purposes). Practical utility of measurement-based decisions (for specified purposes). Social value of the (full set of) consequences associated with the testing program.
How effectively do test results measure what they are supposed to measure?	How suitable are test results for the uses to which they are supposed to be put?	How acceptable is it to implement the testing policy?

In particular, debate over the ethical approach to defining validity has emphasized that, beyond the measurement level and the decision level, lies another level of analysis: the *impact level*. In order to evaluate the overall acceptability of an assessment policy, we need to look way beyond the technical quality of the assessment procedure. We need also to consider all of the consequences that the assessment gives rise to, whether anticipated or unanticipated, intended or unintended.

The idea of an intended impact brings us right back to the purpose of the assessment. It reminds us, not simply that there might be multiple intended purposes for administering any particular assessment, but also that these might include entirely different kinds of intended purpose. Earlier on, we discussed purpose superficially in terms of measurement, then more deeply in terms of decisions. Now, we need to discuss purpose independently in terms of impacts.

Obviously, the intention underlying any measurement-based decision-making is to ensure substantial positive consequences, with minimal negative ones. In other words, good quality decisions, based upon good quality information, ought to reap rewards. As such, the impacts arising from measurement-based decision-making will need to be evaluated: first, in their own right, to check that the anticipated cost-benefit payoff has been delivered; but also, second, because of the relevance of those impacts to the (pragmatic) validity argument. In other words, if the actual consequences of using the educational assessment are in line with the anticipated ones, then this helps to validate the measurement-based decision-making procedure from a purely technical perspective, as well as being reassuring from an ethical one.

In recent years, we have come to recognize (anew) the importance of purposes for educational assessments that are entirely independent of measurement-based decision-making. These intended impacts are presumed to arise directly from the administration of the assessment, or from its anticipation; and they are presumed to arise even if the assessment happens to lack validity from a technical perspective. In other words, these consequences operate independently of the quality of measurement-based decision-making. Such impacts include incentivizing and messaging effects (Haertel, 2013a; Ho, 2014). They have been the focus of considerable attention among scholars working on theories of action related to intended impacts (e.g., Bennett et al., 2011; Carpentieri, 2013; Haertel and Herman, 2005; Lane et al., 1998). Incidentally, when validity is defined straightforwardly in relation to what an assessment practice claims to do (Shepard, 1993), this formally extends the scope of validation research to include evaluations of this sort, in line with the ethical approach described above (Haertel, 2013b).

This chapter began by noting that bad things can happen when we fail to pay sufficient attention to the purpose, or purposes, that an educational assessment is supposed to be serving. These bad things include the following. First, when results from an educational assessment are used for a purpose for which it was not specifically designed, the information captured by those results may be sub-optimal for that secondary use, and this will impact negatively upon the accuracy and utility of the decisions that the results will be used to make.

This might happen if the effectiveness of a primary school were to be judged purely on the basis of aggregated test results, from attainment tests in maths and English, sat by successive (graduating) cohorts of students. It is quite possible that results from those tests could be valid for measuring attainment in maths and English, for individual students, at the same time as being invalid for measuring the effectiveness of the school. After all, there is far more to an effective school than the ability to teach maths and English. Moreover, without using those aggregated results to calculate a progress measure, they would not be adjusted to account for the quality of the school's intake. Clearly, if parents were to decide the most effective school for their children based *only* upon evidence like this, then very many incorrect decisions would be made. The likelihood of errors like these ought to be evaluated and publicized, if decisions like these (based on secondary uses of results) are actually being taken; and especially if these are officially sanctioned uses.

Second, the broader consequences of using results for secondary purposes must also be evaluated. For instance, if parents actually were to use aggregated results in maths and English tests as a basis for school choice, then those results would end up having very high stakes for schools. This would create perverse incentives for schools to do everything in their power to ensure that each graduating cohort scored as highly as possible on the maths and English tests. This might lead to teaching time being directed away from subjects that were not tested; or perhaps to certain important aspects of the curriculum not being taught at all. More worrying still, to the extent that it might be possible to improve scores in maths and English by nefarious means, e.g., by using a variety of questionable drilling or coaching techniques, this could negatively impact the quality of teaching and learning of maths and English.

In short, the greatest risk is not that results from a secondary use might be less suitable for that secondary use than for the primary use (which would be true); nor that impacts arising from the secondary use—e.g., reallocation of curriculum time to maths and English—might make those results even less suitable for that secondary use (which might also be true); nor even that impacts arising from the secondary use—e.g., reallocation of teaching time away from those elements of maths and English that featured least frequently in the tests—might render those results less suitable for the primary purpose as well (which might also be true). The most serious concern is that impacts arising from the secondary use—e.g., a classroom culture that is focused upon attempting to game the tests wherever possible—might come to undermine the pedagogical process itself, meaning that students end up learning less than they would have done, if the secondary use had never been mooted. The bad things that can happen when we fail to pay sufficient attention to the many different purposes of educational assessments—especially accountability related purposes—are eloquently discussed by Koretz (2008, 2017).

Multiple perspectives on purposes

Debates that arise when designing qualifications are useful for illustrating the complexity of policy and practice in relation to assessment purposes. In particular, they emphasize how all three levels of analysis—measurement, decision, and impact—will generally need to be taken into account, simultaneously, when planning how to satisfy a variety of assessment purposes. The issues at stake are partly technical (concerning effective assessment design) but they are also educational, economic, and social. It is not simply that there are multiple purposes for assessment in education, nor multiple categories of purpose, there are also quite different perspectives on assessment purposes. This becomes especially apparent when viewed through the lens of qualification design, because qualification purposes are discussed in all sorts of different ways (Cedefop, 2010), revealing a plethora of ways of thinking about what they need to do.

Three perspectives are especially important: the information perspective (focused on decisions); the engagement perspective (focused on impacts); and the expertise perspective (focused on learning outcomes). To illustrate these perspectives, imagine that a state or country is considering introducing a new suite of vocational qualifications, for 14- to 16-year-olds who choose not to opt for the traditional “academic” route. If different stakeholders were to be asked what they needed these qualifications to deliver, i.e., what the purpose(s) of these qualifications ought to be, how might they answer? It is quite possible that their answers might have much in common. Yet, it is also possible that different stakeholders might have quite different priorities.

An employer, for instance, might prioritize the need for a qualification to provide high quality *information* concerning the candidates who apply for the jobs that they will be advertising in the future. They might have had bad experiences, in the past, hiring ostensibly qualified candidates, who turned out not to have been competent after all. Employers like these need qualifications that they can rely upon, so as not to make costly mistakes when hiring employees. This necessitates high quality assessment information, derived from high validity educational assessments.

A learner, on the other hand, might prioritize the need for the new qualifications to provide high value learning outcomes, to provide them with the right kind of *expertise*, which effectively equips them for both life and work. Indeed, if learners envisaged a world in which they were likely to have to adapt to a variety of different roles throughout their career, switching jobs and possibly also sectors, then this might dispose them toward qualifications based upon broad, transferrable, learning outcomes. Conversely, were an individual employer to offer their thoughts on this perspective, they might argue instead for qualifications based upon narrow, job-specific, learning outcomes. A construction company might therefore prefer the country to be producing a steady stream of fully qualified carpenters, bricklayers, electricians, and so on; certainly not vocational all-rounders, on whom they would need to spend considerable sums of money on additional training to prepare them for specific job roles. As such, even when debating a single purpose perspective, different stakeholders might champion different requirements.

Finally, a policy maker, perhaps keen to tackle decades of high educational drop-out and failure rates, might prioritize a quite different purpose perspective, wishing to maximize the *engagement* of students and teachers with the processes of learning and teaching. For the sake of argument, this policy maker might be fairly ambivalent about the expertise perspective, and the exact nature of the learning outcomes that these new vocational qualifications ought to deliver. Indeed, prioritizing the engagement perspective, they might argue for a guiding principle which states that learning outcomes must simply be motivating for learners, to maximize the likelihood that they do not turn off and drop out. This might lead them to recommend a system that is characterized by choice from a wide variety of optional units, each one targeting a body of content that has been chosen specifically because it has proven to be interesting to teach and to learn (almost regardless of its value in terms of equipping learners for life and work).

It is worth noting that assessment professionals tend to contribute to debates such as these from the information perspective. Assessment is quintessentially a process of deriving information about individuals from evidence of their behavior, so this should come as no surprise. The information perspective establishes the foundational paradigm for assessment in education. Equally, though, assessment professionals should not be surprised when education professionals who work within alternative paradigms prioritize different perspectives. This can be particularly challenging when those other professionals also have a legitimate stake in assessment. Thus, assessment professionals may find it confusing or frustrating that teachers often use assessment as much to reward learners as to represent their attainments, if not more so (Brookhart, 1993, 1994). What these teachers are doing, in fact, is prioritizing the engagement perspective alongside, or perhaps even above, the information perspective. In other words, they are using assessment to facilitate greater engagement with teaching and learning, and not just to measure.

Of course, the “threat” of an end-of-course assessment has always been assumed to serve an important function in motivating students to learn (Latham, 1886). In other words, the engagement perspective has always been fundamental to assessment design. Problems arise, however, when the engagement perspective recommends assessment design decisions that compromise the ability of the assessment to generate high quality information. Even then, it is still possible that a small hit on the technical quality of the assessment might be deemed acceptable, if there were a sufficiently large payoff in terms of teaching and learning.

Taking multiple purposes into account

I began writing on assessment purposes during the early 2000s. Testing had become endemic, in England, by then—involving the vast majority of 7-year-olds, 11-year-olds, and 13-year-olds, each year—and results from national curriculum tests were being used for all sorts of purposes, spread across at least 16 different purpose categories (Newton, 2012a). A House of Commons enquiry report, *Testing and Assessment*, concluded that:

The evidence we have received strongly favours the view that national tests do not serve all of the purposes for which they are, in fact used. The fact that the results of these tests are used for so many purposes, with high-stakes attached to the outcomes, creates tensions in the system leading to undesirable consequences, including distortion of the education experience of many children. [...] In short, we consider that the current national testing system is being applied to serve too many purposes.

HCCSFC (2008a, p. 20).

In response, the Government stated that it did not accept the argument that the tests served too many purposes; and its Office for Standards in Education added that one of the core principles for efficient use of data in government should be “collect once, use more than once” which is how they characterized the situation of testing in England (HCCSFC, 2008b).

Assessment professionals often express concerns over the use of results for multiple purposes, citing maxims like this one, from the current edition of the *Standards*, which echoes the same warning from Lindquist, some 7 decades earlier:

Most educational tests will serve one purpose better than others; and the more purposes an educational test is purported to serve, the less likely it is to serve any of these purposes effectively.

AERA et al. (2014, p. 188).

As we have already seen, there are good reasons for expressing such concerns. Results from assessments that have been designed to serve one purpose may be completely unfit to be used for another purpose; owing to design choices that increase validity in relation to one use of results, but decrease validity in relation to others. Moreover, using results for purposes that were not originally anticipated may not only beg the validity question, but may also result in negative educational and social consequences. The current edition of the *Standards* provides a number of useful recommendations related to the multiple purposes of assessments, including:

The rationale for a test, recommended uses of the test, support for such uses, and information that assists in score interpretation should be documented. When particular misuses of a test can be reasonably anticipated, cautions against such misuses should be specified.

AERA et al. (2014, Standard 7.1, p. 125).

In educational settings, when a test is designed or used to serve multiple purposes, evidence of validity, reliability/precision, and fairness should be provided for each intended use.

AERA et al. (2014, Standard 12.2, p. 195).

An index that is constructed by manipulating and combining test scores should be subjected to the same validity, reliability, and fairness investigations that are expected for the test scores that underlie the index.

AERA et al. (2014, p. 210).

With renewed interest in validity theory in recent years, closer attention has been paid to the challenges of taking multiple purposes into account as a routine component of validation practice, and new tools for thinking about these challenges have been proposed (e.g., Kane, 2006; Zumbo and Forer, 2011; Newton, 2012b; Koch and DeLuca, 2012; Koch, 2013; Ho, 2014).

Taking multiple purposes into account as a routine component of assessment design presents even greater challenges (Newton, 2017b). There will always be trade-offs to discuss, and compromises to be made, and answers will almost never be straightforward. Conversations like these inevitably take assessment professionals beyond their comfort zone, requiring them to engage with

professionals who may think very differently, and value different outcomes. As complex and frustrating as such discussions can be, it is critical that all relevant concerns are aired, from all possible perspectives, for design choices to be made as defensibly as possible.

It seems fair to say that assessment professionals have a tendency to gravitate toward purpose purism, which idealizes the principle that assessment design ought to be driven by a single assessment purpose; after all, that really is the best approach to take, from a purely technical perspective (cf. Baker, 2000). However, a broader, more realistic outlook is captured by the idea of purpose pluralism, which idealizes the principle that assessment design should be driven by a multiplicity of assessment purposes simultaneously (Newton, 2017b). This reminds us that there is far more to assessment in education than can be captured by the “simple” idea of measuring learners.

Introduction

This article is about the implementation of Assessment for Learning (AfL). First, we will discuss definitions of AfL. We will then provide a brief literature review to highlight the potential of AfL, as well as common pitfalls in implementation based on previous research. This literature review will close by providing an analysis of cutting-edge studies focused on successful large-scale implementation of AfL across contexts. Specifically, we will turn to discussing findings from two recent projects conducted in Australian and Canadian schools respectively. This discussion will illustrate some of the most recent evidence and ongoing issues in implementing AfL. Our interest in this chapter is to consider next steps for AfL implementation: What is needed for wider implementation? What systemic pitfalls should be avoided? What gaps in theory exist that limit current AfL uptake? Accordingly, this article concludes with a discussion on potential ways forward in facilitating implementation of AfL in schools.

AfL: what is it?

The term Assessment for Learning gained popularity after the Assessment Reform Group (ARG) proposed it in 1999 and 2002. The ARG was a UK-based group of assessment researchers which aimed to provide evidence-informed recommendations for educational policy and practice in relation to classroom assessment, teaching and learning. Their work built on the seminal [Black and Wiliam \(1998a,b\)](#) review, which showed substantial potential for classroom assessment and feedback (i.e., formative assessment) to enhance student learning outcomes. The ARG claimed that while these research findings were commonly accepted, “the development of practice in this area will need a concerted policy-making push” ([ARG, 1999](#), p. 1). Further, they identified that the term “formative assessment” was often misinterpreted in a way that did little to support student learning. To overcome this issue, they coined a new term for using assessment to promote learning: *Assessment for Learning* (AfL).

The ARG defined AfL as: “the process of seeking and interpreting evidence for use by learners and their teachers to decide where learners are in their learning where they need to go and how best to get there” ([ARG, 2002](#), p. 2). AfL was described as being in direct contrast to *assessment of learning*, which focuses on grading and reporting. To facilitate translation of research evidence to policy and practice, the ARG published a leaflet in 2002 which provided a definition of AfL and outlined 10 evidence-informed principles for classroom practice. The 10 principles state that AfL: (1) is part of effective planning; (2) focuses on how students learn; (3) is central to classroom practice; (4) is a key professional skill; (5) is sensitive and constructive; (6) fosters motivation; (7) promotes understanding of goals and criteria; (8) helps learners know how to improve; (9) develops the capacity for self-assessment; and (10) recognizes all educational achievement (p. 2). Each of these principles was seen as essential to successful implementation of AfL.

In more recent literature, AfL is often described as focusing on a set of five interrelated key strategies (e.g., [Heitink et al., 2016](#); [Wiliam and Thompson, 2008](#)):

- Clarifying and sharing learning goals and criteria for success;
- Gathering evidence of student learning by using informal and formal assessment techniques, such as questioning;
- Providing feedback to students to move learning forward;
- Enhancing student autonomy and self-regulation by engaging them in peer and self-assessment.

When used in combination, these strategies have significant potential to enhance student learning outcomes, motivation and autonomy by (1) making learners aware of learning goals and what quality work looks like, (2) encouraging students to generate feedback about their own and/or their peer's progress in relation to these goals, and (3) assisting students in taking action based on

feedback (Hawe and Dixon, 2014; Hawe and Parr, 2014; James and McCormick, 2009; Sadler, 1989; Wiliam and Thompson, 2008). As students become more autonomous and self-regulating, they become increasingly less reliant on teacher feedback, resulting in more sustainable classroom feedback practices (Hawe and Parr, 2014).

A key point of discussion in the literature is the nature of formative assessment versus AfL. In fact, there is still much discussion about the meaning of both terms (e.g., Wiliam, 2011, 2017). Many have used these concepts as synonymously (e.g., Brookhart, 2019). Yet others have argued that these concepts overlap but also have several distinct features (Swaffield, 2011; Van der Kleij et al., 2015). Although many assessments can be used formatively, AfL is about the day-to-day classroom assessment processes that directly promote student learning. This means that students are the direct beneficiaries of AfL, which is not necessarily the case in formative assessment (Swaffield, 2011). Moreover, they are active agents within the assessment process (i.e., users of assessment information) to benefit their own and others' learning progress. Accordingly, AfL has been termed a "participatory pedagogy" as it draws heavily on social-constructivist principles. In AfL, students learn within communities of practice by actively using feedback (and other assessment strategies) from interactions with themselves, peers, and teachers to develop their knowledge, abilities and skills (Willis, 2010).

Implementing AfL: what we know

Over the past three decades, AfL has been widely promoted in research, policy and practice across the globe. Despite widespread promotion and substantial efforts to translate and disseminate research evidence to policy and practice, many challenges in AfL implementation have been reported. We will briefly discuss predominant challenges reported in the literature.

Although the 2002 ARG definition may seem straightforward, it has come to be interpreted in a variety of ways. One issue is that "the way in which the words are interpreted and made manifest in educational policy and practice often reveal misunderstanding of the principles, and distortion of the practices, that the original ideals sought to promote" (Klenowski, 2009, p. 263). AfL has often been interpreted in a simplistic manner, what has come to be known as implementation of the letter rather than the spirit of AfL (DeLuca et al., 2019; James and McCormick, 2009; Marshall and Drummond, 2006), resulting in practices that have little resemblance to the evidence-informed strategies the ARG sought to promote. For example, Swaffield (2011) reflects on the erroneous interpretation of the original AfL definition as "at what level is the student, what is the [sic] next in the sequence and which learning objectives need to be targeted" (p. 439). This interpretation has resulted in practices with a rigid focus on pre-determined learning outcomes, as opposed to valuing all learning outcomes as per the original AfL definition. This issue is no doubt related to the competing and at times contradictory requirements of AfL versus assessment for accountability (Baird et al., 2014; Cumming et al., 2019).

A second linked challenge observed in the research is the compatibility of AfL with the dominant summative mode of assessment operating in many school contexts. Tied to accountability regimes and the longstanding grading traditions in education, summative assessment often emphasizes tested achievement rather than more comprehensive learning. Several studies have pointed to the challenge of implementing AfL within a summative orientated assessment culture (Baird et al., 2014; Cumming et al., 2019; Shepard, 2000). In instances where AfL prevails, it is often through slow, intentional, and school wide commitments to AfL pedagogies and mandates, where feedback rather than grades is prioritized as central to education (Andersson and Palm, 2017; Hopfenbeck et al., 2015; Marshall and Drummond, 2006). Research evidence suggests that school-wide reform efforts are needed to change the predominant assessment culture in a school in a way that challenges entrenched assessment values, routines and priorities among all stakeholders, including students and parents.

Successful efforts toward AfL implementation—those that promote a spirit orientation of AfL in classrooms—show significant commitment to teacher professional development (Heitink et al., 2016; Hopfenbeck et al., 2015; Lee et al., 2019). Consistent across these studies is that teachers tend to (a) learn collaborative and reflect on their assessment practices in groups; and (b) have administrative support for their professional learning in assessment.

When the spirit of AfL is implemented across classrooms and schools, there is an authentic and embedded use of strategies to promote student learning, autonomy and agency (James and McCormick, 2009; Marshall and Drummond, 2006). Assessment becomes the mode of operandum for teaching and learning. Students ask for feedback and require it to move forward in their learning. Student work (i.e., assessments and learning progression) are highly visible to students, parents, and the learning community to support a continuous conversation about growth and progression. Ultimately, teachers who implement the spirit of AfL lead others in their school both by modeling effective implementation strategies but also through their ongoing professional learning. They continue to ask questions and seek feedback on their own practice as they internalize the principles of AfL to continuously improve their practice (DeLuca et al., 2019). These findings correspond with findings from the broader school effectiveness literature, which highlight the criticality of teacher self-reflection, peer learning and continuous professional learning (Hopkins, 2013; Louis and Lee, 2016).

The edge of implementation: two cases of large-scale implementation

This section describes two cases of large-scale implementation of AfL. This discussion will illustrate some of the most recent evidence and ongoing issues in implementing AfL. The cases will be described individually, followed by a synthesis of what can be learned from these cases.

The Australian case

Assessment for Learning has been endorsed at the national and state/territory levels over the past decades. Despite widespread official endorsement, research suggests that AfL implementation across Australian schools is variable (Birenbaum et al., 2015; Cumming et al., 2019; Van der Kleij et al., 2018). Specifically, researchers have expressed concerns over consistency of practical implementation support. In addition, there are concerns over the nature of AfL implementation in light of accountability pressures. It is against this background that the ARC Linkage project “Improving student outcomes: Coaching teachers in the power of feedback” project (2017–2019) was initiated.

The project examined the impact of a school-wide professional learning intervention in feedback. The intervention was underpinned by a student-centered feedback model (SCFM; Brooks et al., 2021c). Thirteen Queensland state primary schools were involved as partners in the three-year project, which was contextualized in English writing. Each project year focused on a different student Year level, starting with Year 5 (students aged 10–11) and ending with Year 3 (students aged 8–9). The project involved school leaders (principals, deputy principals, and heads of curriculum or leaders in coaching roles) and a sample of at least three teachers in each school per project year.

Within each project year, the intervention took place through externally facilitated school-based collaborative sessions over a six-month period. In these sessions, the external facilitators and school leaders guided teachers through different aspects of the SCFM. The sessions involved discussion of research evidence, discussion of practice in light of this evidence, as well as practical activities, firmly grounded in curricular and assessment planning. Strategies were designed to be effective yet as simple as possible for ease of implementation. Teachers were encouraged to trial strategies in their classrooms using an approach that suited their particular context. The collaborative sessions were followed by scheduled implementation-focused discussions between school leaders and teachers. The external facilitators provided continued on-demand support to school leaders via phone or email in between sessions. The intention was for school leaders to learn alongside teachers while gradually increasing their capability to lead the professional learning within their school.

Although the project name suggests a primary focus on feedback, the intervention comprehensively reflected the spirit of AfL (James and McCormick, 2009; Marshall and Drummond, 2006). The SCFM (Brooks et al., 2021c) which underpinned the project foregrounds the active role of students in realizing the potential of feedback to improve learning outcomes. It places a key focus on enhancing capacity for student autonomy in assessment through self-regulated learning. Students are at the heart of the SCFM, which is made up of two parts, detailed next.

(1) The model’s inner wheel (Brooks et al., 2021c) focused on clarifying success (feeding up), checking in on progress (feeding back) and promoting improvement (feeding forward); based on Hattie and Timperley (2007). These processes capture all strategies typically associated with AfL (Heitink et al., 2016; Wiliam and Thompson, 2008). Intervention strategies for clarifying success included co-construction of success criteria by teachers and students and providing models demonstrating different levels of quality. Checking in on progress involved formal and informal assessment. Importantly, these processes were tightly connected with clarifying success, which enabled identification of key focal quality features. Promoting improvement focused on identifying and enacting strategies and next steps for improvement. All aspects of the feedback cycle involved teachers as well as students, through scaffolded peer- and self-assessment and feedback.

(2) The model’s outer wheel focused on the broader conditions for effective feedback, such as the school culture and teacher feedback perceptions (Brooks et al., 2021c). For example, the intervention focused on shifting school leader and teacher perceptions of feedback as corrective information that teachers provide to students, to jointly constructed notions of what success looks like, how students are progressing, and what next steps are to promote improvement. In addition, the intervention aimed to bring about a shift in the schools’ learning cultures by placing a core focus on continuous improvement and feedback as a powerful learning tool.

Project evaluation drew on various qualitative and quantitative data sources, including focus group and individual interviews with school leaders, teachers, and students, as well as classroom observations, field notes, teacher and student self-report surveys and student assessment scores. Each project year had a slightly different evaluation focus to enable comprehensive analysis of evidence and triangulation of findings. It is beyond the scope of this article to discuss all findings in depth (a full list of papers based on this project is available from the first author upon request). Rather, key findings pertaining to AfL implementation will be highlighted here.

Overall, the results showed substantial potential for this type of professional learning. Although shifting perceptions of feedback from transmissive to student-centered took a considerable amount of time, many school leaders identified that the impact of the professional learning on classroom practice had been “massive”. For example, school leaders reported that the intervention had resulted in stronger alignment of teaching and feedback to student learning needs as aligned with curricular assessment standards. Many teachers reported that the intervention had substantially changed their classroom practices. One teacher reflected that they now used strategies that were “much more effective; and really simple and easy to use.” Although teachers were initially hesitant to open up their classrooms for peer observation, such observation was highlighted as one of the most powerful levers for collaboratively bringing about changes in classroom practice.

Findings across all project years highlighted the criticality of clarifying and co-constructing of assessment standards and criteria. Through the intervention, teachers were challenged to jointly construct more in-depth understandings of curriculum standards and success criteria (Brooks et al., 2021c). For example, school leaders and teachers highlighted the value of collaborative discussions focused on the curriculum and pedagogy (Brooks et al., 2021b). Another school leader reported that teachers developed a better understanding of the nature of learning progression in English writing, which resulted in teachers better tailoring their lessons to

student needs: “checking-in in formative ways, along the way; and then tweaking and refining and moving their teaching more regularly.” Having a better understanding of curriculum requirements also resulted in stronger teacher agency and more meaningful curriculum implementation.

Further, in-depth teacher understanding of curriculum standards and success criteria was foundational to nurturing student agency and self-regulated learning, through processes such as co-constructing success criteria with students (Brooks et al., 2021c). Through the intervention, teachers were encouraged to co-construct the most important success criteria with students. One teacher reflected: “we have cut down the success criteria and made it really—like, instead of having all those huge success criteria for them, it’s two/three things, ‘This is what’s important’”. Student understanding of success criteria was foundational to activating them in the assessment process, through the use of models and peer and self-assessment. These enhanced understandings also fostered self-regulated learning, enabling students to identify how they were progressing and what next steps they needed to take to improve, providing a motivational mechanism. For example, one student reflected on clarity of criteria for the A-E curriculum achievement levels: “A, B and C’. And they have got certain things in them. And if you meet those things, that’s the [sic] great ... and trying to get it better every time.”

Another key finding based on data from the second intervention year was students in the intervention group made substantially larger achievement gains than those in the comparison group (Brooks et al., 2021a). These findings add important insights to the evidence-base on AfL, demonstrating the benefits of a genuinely student-centered approach. In addition, these findings provide support for the notion that AfL can be beneficial even for young students. When given adequate scaffolding tools and support, students as young as eight were capable of self-regulating their learning and effectively using self- and peer assessment (Brooks et al., 2021c). For example, one Year 3 teacher reflected: “I honestly did not think that they would give very good feedback to each other. I didn’t think they would; and they have.” Seeing the impact of student-centered practices on student learning propelled teacher buy-in and commitment to the project.

Although the project overall was impactful, the extent to which the intervention resulted in practices that can be classified as the spirit of AfL varied across schools and classrooms. There are many possible reasons for this. The main reasons are discussed next.

Teachers had different levels of knowledge and experience prior to the intervention, with some more open to trialing student-centered strategies than others. Of note, activation of students is dependent on teacher willingness and capacity to step away from the traditional model of the teacher as an expert who tells students what to do. A teacher reflected: “I usually try and give them leading questions. So I might say to them, ‘How do you feel when you are reading this?’, ‘How would someone else feel when they were reading this?’ I sort of tend to try and make them more active, rather than me just saying, ‘You need to go and work on this.’” Further, some teachers reported explicitly communicating expectations for the learning culture to students, for example stating, “that they are in charge of their learning and that it’s not just me standing at the front and telling them what to do.”

Most school leaders participated across the three project years, resulting in a substantial expansion of their knowledge of effective feedback. However, the extent to which the intervention resulted in school leader understanding of fundamental ideas of AfL was variable; some leaders continued to focus on strategy compliance rather than fostering genuinely student-centered classroom practices. Further, there was considerable variation in school leader capacity and confidence to co-lead the professional learning, with some identifying a perceived lack of leadership skills.

A core focus on collegial support and collaboration appeared to have fostered implementation, with some differences observed in collaborative practice across schools. These targeted opportunities to collaborate were made possible by school leader commitment to the project. Interestingly, teacher and school leaders in two school pairs reported having benefited from inter-school collaboration. A related finding was that having developed a common language to talk about processes surrounding learning at the classroom and school levels appeared to have strengthened implementation.

At the conclusion of the project, schools appeared to be at different stages of scaling up AfL practices to become school-wide and embedded across the curriculum, with each school taking a unique approach. Schools where AfL became a core focus of collaborative planning processes appeared to have most success in gradually scaling up implementation. Participants perceived that the intervention’s focus on evidence-informed practice as embedded within the writing aspect of the English curriculum aided implementation. Yet, it was up to school leaders and teachers to broaden implementation to other classrooms and curriculum areas; one of the key remaining challenges at the conclusion of the project. Interestingly, some teachers reported that students became highly accustomed to the new student-centered practices, resulting in changed student pedagogical expectations. A such, a sense of students holding teachers accountable for broader implementation of AfL emerged.

The Canadian case

The second case of large-scale AfL implementation is from Ontario, Canada where two school districts participated in a three-year Ministry of Education endorsed professional learning program aimed at building systemic capacity in AfL, and specifically teachers’ adoption of AfL strategies across elementary and secondary classrooms. Within the Ontario context, there is a robust policy framework that articulates assessment as a core element of teaching and learning. Within the guiding document, *Growing Success: Assessment, Evaluation and Reporting in Ontario Schools* (Ontario Ministry of Education, 2010), assessment is described as primarily serving the improvement of student learning with definitions and practices articulate for assessment of, for, and as learning.

Within this specific professional learning case study, teachers and school leaders, were focused on deepening their understandings and pedagogical commitments to AfL as articulated in the *Growing Success* (2010) document and as supported by the *Assessment Reform Group’s* (2002) initial definition and further operationalized through *Wiliam and Thompson’s* (2008) five

assessment-based pedagogies as outlined above (see the *What is AfL?* section). Within this broad AfL framework, teachers and school leaders pursued specific learning goals that were relevant to their instructional and school contexts, to engage in cycles of inquiry.

The two partnered school districts, one public and one Catholic, were in the same geographic region and involved a total of 12 schools. Throughout the three-year professional learning project, a total of 12 school principals and 88 teachers were involved (51 from one district and 37 from another). The professional development project was purposefully designed to leverage several key aspects known in the literature to support teacher learning, detailed next.

First, teacher learning was supported by a variety of planned and resourced methods including whole group learning sessions that provided structured learning and reflection time, smaller group learning sessions that allowed for in-school monitoring and support of teacher learning, access to school district assessment coach to support teachers' individual AfL planning and implementation, and structured teacher reflections to enable tracking of performance and growth. In-school teacher learning was also supported by an instructional rounds model where teachers would observe one another implement AfL strategies and provide supportive feedback for improvement. The process and impact of this strategy in this professional learning program is further detailed in [DeLuca et al. \(2015\)](#).

Second, teacher learning of AfL principles was paralleled by administrator (i.e., school principal) learning of AfL. While teachers were learning to implement AfL in their classrooms, their school principals were learning to implement AfL as strategy to support their teachers' development (i.e., as a strategy for leadership and staff development). This parallel learning was intended to not only lend administrator support to the initiative and to teachers' professional development was also intended to take "formative assessment schoolwide" by establishing meaningful learning partnerships between school leaders and teachers to form a genuine learning community with and across schools in the two districts ([Moss and Brookhart, 2009](#), p. 137).

Finally, a key advantage of the program was that it was supported by the Ministry of Education and the two school districts for three years, providing prolonged exposure to the various resources, professional learning structures, and learning goals of teachers, school leaders, and school districts. As previous research has repeatedly shown, AfL is not a practice that can be cultivated and internalized quickly, either among teachers or their students. As such, the three years allowed for teachers to develop skills, reflect on their progress and setbacks, and see the impact of their efforts on students and school assessment cultures. Specifically, data were collected through a variety of qualitative and quantitative measures to trace teacher learning in AfL over the three years. Instructional rounds sessions and classroom instruction were observed to determine how classroom assessment practices changed for 18 focal teachers. Semi-structured interviews were also conducted with these teachers repeatedly to detail their changing conceptions of assessment and learning progression. All teachers were invited to complete yearly surveys that focused on their professional development in assessment and changes to their assessment practice. These surveys were coupled with student surveys on classroom assessment practices (see [DeLuca et al., 2018](#)). In a companion paper, we detail the professional learning continua teachers experienced throughout the three-year project to demonstrate the growth potential in such a model (see [DeLuca et al., 2019](#)).

In considering the systemic challenge of AfL implementation, as posed in this article, from this case we draw out three important themes. The first of these themes is professional accountability. Embedded in this case were multiple points and people to whom teachers were accountable for their learning, including themselves and their students. Defined by [LaPointe-McEwan \(2018, p. 115\)](#) as "constructive in nature" professional accountability is about owning one's learning goals and narrating a learning journey to key stakeholders to fuel continued development through feedback and encouragement. Throughout this project, teachers, perhaps more so than school principals, were able to demonstrate their learning in action through the instructional rounds process and reflect on their progress in small and large group learning sessions. The district assessment coach also served as a professional accountability partner to sustain teacher learning throughout the project. As the project progressed teachers commented that students also began to expect AfL activities and practices, asking for peer, self, and teacher feedback; thereby serving as yet another source of professional accountability.

The second theme that contributed to program success was systemic commitment to AfL learning. While teachers were learning alongside their peers, school leaders (i.e., principals), and district assessment coaches, Ministry of Education staff also participated in large group learning sessions, typically as co-facilitators but also as co-learners. As such, from ministry to teacher there was continuous learning about AfL across various educational roles within the system, which provided fertile ground for deep conversations, reflections, and connections. Further to these stakeholders' engagement in the project was the research team who contributed an additional layer of AfL learning to the project, adding layers of commitment to a professional learning project substantiates its value and increases energy for participation. In this case, there was a purposeful move from schoolwide learning to systemic learning, which motivated learning for those involved in the project.

Finally, success for many teachers and administrator came when they realized that AfL applied equally to their learning as to their students' learning. To this end, the program was predicated on high levels of non-evaluative feedback, a hallmark of the instructional rounds approach ([City et al., 2009](#); [Marzano, 2011](#)). When teachers began utilizing the AfL principles intuitively to guide their own professional learning and to provide meaningful feedback to one another, they could see its application more clearly to their classroom teaching context. Their own professional learning became yet another context to practice AfL and deepened their AfL skills, knowledge, and questions. Fundamentally, as the project progressed two components of AfL began to take hold: (1) teachers and school principals became better able (and more comfortable) at providing constructive and valuable feedback; and (2) their questions about AfL became more nuanced, critical, and generative. Both of these components led to greater gains in learning.

Learning from the cases

Although both cases describe unique projects across different international contexts, there was a substantial degree in commonality of focus and outcomes. Hence, a cross-case analysis provides insights into common findings to show what worked to facilitate implementation of AfL.

Findings from both cases highlight the importance of considering the temporal dimension of AfL implementation. Both projects were conducted across a three-year period and showed that participants gradually deepened their understandings and shaped their practices over this period of time. This finding has important implications for anyone willing to implement AfL. It shows that the implementation process is likely to be gradual, for teachers as well as for students. At times, implementation may also require taking steps back before moving forward. For example, the Australian case highlighted the need for teachers to take a step back to more closely examine curriculum expectations, before clarifying what success looks like with their students. Although all of this takes time, it vitally underpins successful AfL implementation.

Further, both cases highlight the interplay between actors within different layers of the education system. Although AfL ultimately concerns students and happens in day-to-day classroom practice, these cases show that implementation requires a focus beyond the classroom. We conclude that AfL needs to be viewed as embedded within a multilayered community of practice. Several key findings pertain to this multilayered contextual dimension.

Across both cases, implementation of AfL reflected the very nature of AfL, with school leaders, teachers and students learning alongside one another. Although school leaders and teachers were at different qualitative stages of implementation, they continuously reviewed and refined their practices, taking it one step at a time. This was exactly the approach taken with students. As illustrated by the Australian case; rather than showing students a model of high quality, teachers worked with students to work out where they were currently at, and aimed to progress their learning by helping them identify next steps on the road to improvement. School leaders, teachers and students all gradually became more proficient and confident in enacting AfL.

Interactions between actors in different layers of the education system played important catalyzing roles in AfL implementation. Establishing a learning culture and common language to talk about learning was one important driver of implementation. Further, professional accountability functioned as an important lever for AfL implementation by enhancing commitment of actors at different layers of the system. Teachers and school leaders were accountable to each other, external partners, as well as students in their schools. In these cases, external experts played an important role in initiating conversations using a shared language, challenging previous conceptions and holding teachers and school leaders accountable for implementing learnings from the professional learning intervention. Yet, we believe that even outside a funded professional learning intervention, the same can be achieved when there is a clearly articulated vision and articulation of intention across the school.

As previously identified, teachers needed time to figure out what AfL might look like in their classrooms, which took time. The cases showed that a deep understanding of why AfL results in improved student learning fostered teacher agency and depth of implementation. Teachers particularly valued being able to see what a particular strategy might look like in action, either through expert demonstration or peer observation and discussion. Middle leaders and coaches played a vital role in connecting theory and practice. These findings further highlight the importance of school-wide and/or systemic support structures. For example, principals in both cases set aside time for teachers to learn about AfL, reflect on practice and plan for implementation. This signals to teachers that engaging in in-depth AfL practice is valued and meaningful. The cases thus provide compelling evidence of the importance of school leader commitment and the provision of organizational strategic support. Importantly, collaboration does not need to be limited to the bounds of the school; both cases highlight the potential of cross-school collaboration.

Across both cases, teacher learning and implementation was propelled by seeing the impact of changed classroom practices on student motivation, agency and learning outcomes. As argued by Hattie (2012), seeing the impact of one's practice on students is one of the most important drivers of teacher motivation to continuously improve their practice. Coupling professional learning with active research and evaluation allowed for teachers and school leaders in these two cases to see the gains their learning was having on students. In many ways, this partnership between research and professional learning leveraged a key AfL strategy; to make visible the learning for the learner.

The cases also highlighted the contextual nature of AfL within subjects. These findings attest to the notion that generic principles are insufficient to meaningfully guide AfL practice (Hodgen and Marshall, 2005; James and McCormick, 2009; Van der Kleij et al., 2018); teachers need more specific guidance which shows what this might look like in their or across different curriculum areas. Within the Canadian case we saw that teachers had latitude to narrow their focus of learning to their own context of teaching. As such, a primary task of their professional learning was to translate, with support, general AfL principles into context and disciplinary specific actions. Going forward it may be useful for researchers and the policy community to provide teachers with greater granularity in the application of AfL principles across teaching and disciplinary contexts.

Future implementation

In writing this article, we set out to consider what was required for systemic adoption and implementation of AfL. From the two cases presented, and corroborated by the literature, it is clear that several structures influence AfL uptake across schools. At the heart of these factors is a drive to change the culture of assessment in schools—largely from summative motivators toward feedback-driven teaching and learning (Laveault and Allal, 2018). Changing assessment cultures takes time and dedication by stakeholders

across system levels - teachers, school leaders, and policy makers. Involvement of students and parents is also critical, and will often follow once systemic changes have been achieved. Centrally, the structures known to shape systemic AfL implementation are:

- (a) Facilitating co-learning and co-commitment to learning by classroom teachers, school leaders, and where possible, policy makers;
- (b) Facilitating cycles of application, observation, and reflection (i.e., providing opportunities to implement theory in practice with feedback and to reflect on implementation practices);
- (c) Enabling teacher autonomy to narrow and specify learning goals to their unique teaching contexts while maintaining broad alignment with systemic goals of school districts;
- (d) Leveraging systemic and district policies that support professional learning aims and that build coherence across schools' and teachers' professional learning goals;
- (e) Coupling professional learning initiatives with research and evaluation activities to make visible for teachers and school leaders the effects of teacher change on students' and school assessment culture; and
- (f) Investing in longitudinal professional learning programs that are resourced for proactive and sustained teacher development.

Through such structures, there is evidence that communities of professional learning emerge, and new assessment practices and cultures flourish within schools.

What remains less well established in the literature, and which requires greater action by both educational researchers and policy makers, is (a) the narrowing of broad AfL principles to diverse teaching contexts and disciplines, which would enable teachers to gain greater clarity on the application of AfL across teaching contexts; (b) the charting of school leader and school system progressions of AfL adoption and growth in order to make visible how entire systems ebb and flow as they strive toward greater implementation; and (c) the development of robust policies aimed at teacher professional learning that make progressive provisions for teachers' intensive training in key competency areas, such as assessment. To this final point, building more consistent policy narratives that establish congruence between various assessment mandates across the system (i.e., formative, summative and large-scale) and that couples such mandates with provisions for teacher professional learning would enable a progressive policy response that functions as a productive foundation for systemic AfL implementation.

In order to move forward with AfL adoption at scale, it is clear that a multi-layer, strategically resourced approach is required that involves key stakeholders in progressive and sustained learning. Additionally, policy and research must continue to advance models that make visible what systemic AfL looks like in terms of resources, policies, and professional learning commitments.

Acknowledgment

The "Improving student outcomes: Coaching teachers in the power of feedback" project (2017–2019) was supported by the Australian Government through the Australian Research Council [LP160101604].

For every complicated problem, there is a solution that is short, simple, and wrong.

H. L. Mencken (1880–1956).

Aim of the chapter

This chapter addresses political concerns raised about education worldwide the last decades. Many countries, including Norway, have developed *school contribution indicators*, statistical measures of how much “the school” contributes to students’ learning, or the schools’ “value added” (Adnett et al., 2002). As these indicators reveal that schools’ contributions differ, the Norwegian Government in 2019 appointed an Expert group on schools’ contribution. The group’s mandate stated that, compared to other nations, social differences are small in Norway, but also here, a systematic connection is found between students’ home background and their learning outcomes. The Expert group published two reports (Lillejord et al., 2020, 2021). The first gave the background for the interest in the school’s contribution to students’ learning and policy initiatives taken in relation to this. The second drew on data from school visits, where the Expert group had dialogs with school leaders, local administrators, teachers, and students, about how they engage in quality development. The chapter starts where the Expert group started, with the so-called Coleman-report, often labeled a “watershed” report (Barr and Dreeben, 1977; Kantor and Lowe, 2017) because it reformulated what was meant by equal education, or at least how it should be measured.

Economists used the Coleman-report to juxtapose schools to firms and introduced the concept *education production function*, equaling students’ learning outcomes to businesses’ profits. The quest for simplicity in this black-box-thinking was accompanied by traditional, somewhat outdated policy assumptions about teaching and how people learn. Based on the idea that investment in human capital will boost the knowledge economy, the OECD launched PISA in 2000, to prepare member states for increased global competition. The focus on human capital and cognition favored individual learning over the school’s social mandate. By interpreting human capital as individual cognitive skills, only half of educations’ *raison d’être* was emphasized, and this policy favored those students who needed it the least. In conclusion, it is argued that to hold teachers accountable for results of work processes that they do not control is a short-sighted, simple, and wrong solution. A better idea is to strengthen the teaching profession and educational knowledge at all levels.

The “Coleman report”

In 1966, sociologist James S. Coleman and colleagues published *Equality of Education Opportunity* (Coleman et al., 1966). The report was massive (Hill, 2017), with data from 4000 schools, 66,000 teachers, and almost 600,000 1st-, 3rd-, 6th-, 9th-, and 12th graders. It revealed a segregated US education system that favored white children in school facilities, class size, and the availability of advanced coursework; and race-based inequality on tests of academic achievement. What mattered more than the conventional measures of school quality were the socioeconomic backgrounds and educational aspirations of classmates, students’ sense of control over their own destinies, and, most importantly, the socioeconomic background of the individual child. In other words, the research team found small effects of school resources and facilities on students’ achievement, relative to those of family background.

These findings were misinterpreted as having shown that schools did not matter or had no effect on student achievement (Barr and Dreeben, 1977; Sørensen and Morgan, 2000). Fifty years later, Downey and Condrón (2016) found still no consensus among scholars regarding the relationship between schools and inequality. They asked if sociologists tended to perceive schools as engines of inequality and suggested a more balanced perspective because schools might reproduce or exacerbate some inequalities, while

compensating for others. Barr and Dreeben (1977) raised concern about research that examined school effects using what they called a quasi-production function formulation to examine the connections between school resources and achievement. In this tradition, from economics, schools were analyzed as firms which transform inputs (resources such as books, teachers' time, activities, and equipment) into outputs (such as increments of knowledge, change in attitude, or gains in achievement).

A driving force in the production function research was Eric Hanushek, senior fellow at Stanford University's think-tank Hoover Institution. In the wake of the Coleman-report, Hanushek (1971) argued that more knowledge was needed about the relationship between inputs and outputs of the educational process. His main goal was to estimate the relationship between educational output and variables which can be controlled by public policy, by addressing three fundamental educational policy questions: (1) do teachers count? (2) are schools operated efficiently? (3) what characteristics of teachers and classrooms are important? Based on equations such as this:

$A_{it} = f(A_{it*}, B_i^{(t-t*)}, P_i^{(t-t*)}, I_i, S_i^{(t-t*)})$ Hanushek (1971, p. 280) concluded that teaching experience and graduate education do not contribute to gains in student achievement scores. Later, Hanushek (1979, p. 355) described education as a "service" which transforms fixed quantities of inputs (i.e., individuals) into individuals with different quality attributes. Since the Coleman-report, he argued, the policy relevance of input-output studies has led to a rapid growth in number of studies with contradictory results. He therefore suggested, as a next step of statistical inquiry into the education process, the education production function (EPF), based on the following argument: All students of economics are introduced to the concept production function, that describes the firm's maximum output feasible with different sets of inputs. Firms are attempting to maximize profits, and a production function represents the maximum achievable output for given inputs. Hanushek described the production function as a powerful pedagogical tool since it provided a basis for describing efficient production in all industries, steel industry as well as education industry.

Hanushek found it unfortunate that EPF-studies were statistical analyses, with few measures of the quality of education, since the most pressing policy questions concern how to improve the quality of education. He regarded cognitive skills the chief measure of educational quality, probably the most important outcome of schooling in determining individuals' future success (Hanushek, 1979, 357) and formulated this definition of teacher quality: good teachers get large gains in student achievement for their classes; bad teachers are just the opposite (Hanushek, 2002, p. 3).

A recurring theme in his research was cognitive skills. Hanushek and Woessmann (2015) saw a direct link between a country's prosperity and the skills of its population and argued that nothing is more important to the future knowledge capital of nations than the cognitive knowledge, and skills, of those being educated today. They assumed a causal relation between the level of human capital acquired by individual students and a nation's economic growth. The greater investment in human capital, the larger gross domestic product (GDP). While this assumption was never tested, policymakers appear to have found the idea compelling.

Vanderberghe (1999) described the education production functions debate as problematic, because researchers used different proxies of educational achievement. Some referred to test results, others to wages. He also problematized human capital theory's "black box" approach to education because it assumes that schools and teachers have no objectives of their own, regards educational institutions as passive, mechanically responding to their "clients," and as not submitted to any constraints.

With increased globalization and the emerging knowledge society (Stehr, 1994), politicians' understanding of the purposes of education gradually shifted. Ydesen and Bomholt (2020) showed how the Organization for Economic Cooperation and Development (OECD) since its inception in 1961, promoted a global vision of education as a source of human capital needed to deal with social challenges and improve the economies of member-states. Education was a prerequisite for nations' "global survival" and global actors, such as the World Bank and the OECD, took the stage as educational experts, focusing on efficiency, and social equity. To oversee that educationalist did their utmost, *accountability* was a favored policy tool.

Economists understood knowledge as the cognitive capacity of the individual student to respond to tests and education as a tool for maximizing the outcomes of the available human resources. In this logic, higher test scores indicated more knowledge stored in individual students' brains. Instead, Stehr (2003), proposed to define knowledge as a *capacity to act*. This is more in line with how modern educational institutions prepare their students, better aligned with cognitive psychology (Sloman and Fernbach, 2017) and in congruence with how Coleman (1988) described the potential of social capital. As the next section shows, a central tenet of the accountability movement was that it *reduced* complexity—by ignoring it, by equaling schools to businesses and by reducing learning to individual, cognitive activities.

The accountability reform movement

Half a century ago, Dalton (1972) warned that any method of educational accountability was likely to be fraught with difficulties because time is spent on measurement and evaluation instead of on the quality of teaching and learning. While questions such as accountable for what, how much and to whom appear simple, they take on a complexity hitherto unmatched in education, he argued. The US report *A Nation at Risk* (National Commission on Excellence in Education 1983), initiated a period of mistrust in schools and introduced policies that supported traditional, teacher-led instruction and ignored the dual function of education—as an individual and social endeavor—to both prepare students for society and improve their learning outcomes. In an early account of US accountability reform, Kister (1993) described how states were required to adopt systems of outcomes-based standards and measures of performance. A decade later, Darling-Hammond (2004) reported that virtually all states were creating new curriculum frameworks and standards for student learning. Outcomes-based education was assumed to help students develop

essential occupational 21st century skills, such as higher-order thinking skills, and be prepared for the demands of the new economy.

In a review of research on accountability reform, Wang et al. (2006) identified a polarized debate around four controversies: Assessment-driven reform, standard-based assessment, assessment-centered accountability, and high-stakes consequences. In the US, standardized assessment, defined as a large-scale, externally developed, and mandated, uniformly administered, and scored evaluation of student learning, had characterized education reform from the late 1800s Committee of Ten, to the National Defense Education Act in the 1950s, the Elementary and Secondary Education Act of 1965, A Nation at Risk in 1983, the Goals 2000 in 1994, up to No Child Left Behind (NCLB) Act of 2001. Each emphasized standardized assessment as a reform catalyst and quality control mechanism. Wang et al. (2006) argued that it is a formidable task to set reasonably attainable standards that can be measured reliably and validly and can challenge all students. Few researchers have publicly defended standardized testing (e.g., Cizek, 2001; Phelps, 2005) and measurement professionals who know and make standardized tests have largely remained silent (Cizek, 2001, p. 20). Therefore, Wang et al. (2006) suggested that future test designs should involve teachers and cognitive-developmental and social psychologists.

With respect to who is holding whom accountable for what, differences are noted among legal, professional, or market accountability systems and administrative/bureaucratic accountability. Based on an assumption that information, its existence, and usage, is key to improving schools, O'Day (2002) studied how information travels through complex systems. She found that the combination of administrative and professional accountability presents a more promising approach for lasting and meaningful school reform than the outcomes-based bureaucratic accountability approach where the emphasis is on student outcomes, and consequences attached to performance levels.

The accountability movement, argued Ingersoll and Collins (2017), assumed that low-quality teachers and teaching explain inadequate school performance. Because teachers too often are not held accountable, they simply do what they want behind closed classroom doors. Tröhler (2017) labeled such unfounded assumptions about education, teachers and school leaders, *organized mistrust*. Onora O'Neill (2013) called for a more *intelligent* accountability, characterized by *intelligible* information that can help stakeholders make informed judgments. She argued that systems of accountability are *second order* ways of using evidence of the standard to which *first order* tasks are carried out for a great variety of purposes. The distinction between first- and second order constructs was initially developed by Schütz (1962). He labeled words and concepts used by actors *first-order constructs*, while the researchers' interpretation of the informants' explanations was second-order construct. Researchers try to ascribe meaning to actors' descriptions, meanings that reach beyond contexts, to make them more general so that they can be part of a theory (Aspers, 2009).

Holding teachers accountable

For decades, teachers have been held accountable by highly abstract information generated by standardized tests. Berliner (2020) explained how he suddenly realized that the OECD-developed Program for International Student Assessment (PISA), is merely another Standardized Achievement Test, because like other Standardized Achievement Tests (SATs) PISA adheres to certain principles of design, have similar correlates, and limits on the interpretations of the results obtained. A problem with standardized tests is that teachers are held accountable for data at an aggregated level, generated through equations that very few people understand. This abstract, second-order information has a summative, restrictive function that is not necessarily helpful for teachers who deal with people in complex, contextual, first-order situations.

In the USA, noted Ingersoll and Collins (2017), teachers have been blamed for the erosion of economic competitiveness, the decline in student academic achievement, teenage pregnancy, juvenile delinquency, a decline in morals, gender and racial stereotyping and discrimination, and on and on. Lillejord (2020) traced the mistrust in teachers, teacher education and the education system to the 1983 report *A Nation at Risk*, commissioned by the US president Ronald Reagan, and the UK election of Margaret Thatcher as Prime Minister in 1979. *A Nation at Risk* claimed that because too many did the minimum work necessary, the ideal of academic excellence as the primary goal of schooling was fading across US education. Both Reagan and Thatcher were proponents of *neoliberal* policies that applied the logic and rules of market competition on the public sector. The goal was to dismantle economic and social structures that obstructed the market and let the "cleansing waters" of marketplace competition eliminate "inferior" schools (Hess, 2001). An individualized, consumer-driven, free market choice approach that superseded the democratizing function of public schools, led to a commodification of educational knowledge (Ball, 2010).

The key discursive strategy in the UK, argued Beck (2008), was to delegitimize teachers through "discourses of derision" (Ball, 1990) and marginalize organized groups representing teachers. Exley and Ball (2011) described UK conservative education policy as founded on the neo-liberal belief in markets and a minimal state. The Conservatives believed in traditional, "old" teaching methods, "real subjects," detailed instruction over what should be taught in schools and surveillance from above. Parents were consumers of educational services and schools subject to market accountability. Pupils succeed thanks to ability, hard work and traditional teaching methods. Where they fail, it is because they, their families or their teachers have not tried hard enough.

Not just teachers and schools were under attack. In England, educational research was criticized for being fragmented, noncumulative, methodologically flawed; often tendentious and politically motivated (Biesta, 2007). It did not provide the answers policymakers needed or equip educational professionals with clear guidance for their work. In the US it was decided that large-scale effect studies were the only form of research eligible for government subsidies (Berliner, 2002). While researchers agreed that

more rigorous research was needed, they argued that there is still a need for correlational, descriptive, and other disciplined inquiry in education (Slavin, 2002). Lareau (2009) noted that politicians' emphasis on scientific *rigor* and references to a *gold* standard left little room to discuss the relevance of randomized controlled trials (RCTs) for education. This approach, she argued, cannot answer the most important questions in education, as advocates of RCTs have misunderstood the research model and misapplied it to the field of education. The idea was simple: when schools are being told what is proven by research to yield the best results or effects, they implement this practice. This simplistic idea, however, does not work, argued Biesta (2010). The introduction of standards and best practice influenced the training and daily work of principals, often practiced as a controlling mechanism that encouraged a narrow "tick box" approach (Cowie and Crawford, 2007).

To sum up, policymakers have tried to solve problems in education by applying a *deficit* perspective and an individualized understanding of education. They have treated schools as private businesses and assumed that schools lack the necessary knowledge and skills and are in desperate need of external assistance. The individualized deficit perspective, combined with organized mistrust, has separated people from each other and eroded the educational system's social fabric. An alternative approach for policymakers who see weaknesses in schools, is to *strengthen* education. Strengthening educational research and the education sector supports knowledge development and contributes to restoring trust among actors and between levels. This is elaborated in the next section, where findings from the Norwegian Expert group on schools' contribution is presented.

Expert group on schools' contribution to students' learning

The case used in this chapter is from a policy experiment (Lillejord et al., 2021). The groups' mandate was anchored in politicians' concern that in Norway, albeit to a lesser degree than in many other countries, family background is the most significant predictor for students' learning outcomes. Along with several other countries (Grek and Ydesen, 2021), Norway has developed *indicators* that measure the school's contribution to students' learning. These indicators show that schools contribute in varying degree to students' learning. On this background, the Government appointed an expert group with a mandate to generate knowledge about how local administrators and schools can enhance their systematic quality work.

A group with varied background and experience was nominated, to identify how schools and local administrators can work systematically to increase students' learning outcomes. The expert group was assigned two tasks: First, to establish a knowledge base on quality work in schools and publish a report on the findings. Second, to visit schools and have dialogs with teachers, students, school leaders and local administrators, to learn how they organize and engage in quality work. Along with Denmark, Finland, Iceland, and Sweden, Norway belongs to the Nordic region, where education is influenced by the German *Bildung* tradition, described by Herdt (2019) as rooted in Enlightenment ideals of freedom and liberation; that sees education as the forming of humanity. A person of *Bildung* can make sound judgment, demonstrate civil courage, and take responsibility for her own life rather than leaving this in the hands of paternalistic authorities. The National Norwegian Curriculum emphasizes the schools' *double mandate*: *Bildung* and students' learning outcomes.

As the mandate was anchored in Norwegian politicians' concern about the persistent "effect" of socio-economic background (SES) on students' learning, the group used the Coleman report (Coleman et al., 1966) as starting point. The mandate expected the group to describe activities in schools and municipalities that enhance students' learning and advice on how schools with low contribution to students' learning can improve their work. Surprisingly, the school contribution indicators were not sufficiently robust to select schools. They were therefore identified by students' grades, national test results, indicators, and other available measures such as student and parent satisfaction and level of bullying in school. Eight schools were selected and paired in four categories, based on their results the last 5 years:

Two schools with substantial contribution to students' learning the last 5 years
 Two schools that contributed to students' learning the last 5 years, with many students from homes with low SES
 Two schools with progression to students' learning the last 5 years
 Two schools with low contribution to students' learning the last 5 years

Fall 2020 and spring 2021, during the Covid 19 pandemic, members from the expert group visited eight primary schools all over Norway, from the north to the south, east, and west, and interviewed local administrators, school leaders, teachers, and students. They all got the same questions. Members of the expert group facilitated the dialogs, and notes were taken both by individual group members and the groups' secretariat. The day after each school visit was used to compare notes and write up a document for each school.

The expert group's main finding was that the schools' contribution to students' learning is primarily a question of leadership and organization. Schools with a substantial contribution to students' learning (the last 5 years) worked *with* complexity instead of reducing it. They were extremely loyal to the schools' double mandate, showed a deep respect for the school's knowledge and practiced a high degree of student participation. These schools regularly evaluated and developed practice as one intertwined process. Leaders assumed that the knowledge needed to develop quality was in the school, and teachers were empowered to lead the professional learning communities, in close collaboration with the school leadership. Information flow was systemic. In one school, an

assistant school leader surveilled all available data and met regularly with the teachers to discuss pedagogical and organizational implications of the data. Joint decisions on which actions to take, were swiftly implemented, and students kept in the loop by their teachers.

In these schools, students, teachers, and leaders worked inquiry based. They continuously developed knowledge about practice and used it to improve practice. Leaders and teachers took for granted that students need a safe learning environment if they are to concentrate on learning. They therefore started with establishing a social foundation for teaching and learning. Everyone was perceived as a resource—for each other and to the school. Each student had a learning partner. If a student struggled with a task, he or she would ask the learning partner. If the partner could not answer, they both approached the teacher to get the help they needed. This is but one example on how the organizational structures aimed at minimizing vulnerability. In these schools, the focus was on learning for all, and no one was exposed or left alone. There was no “my” students and “your” students. All students were the responsibility of all employed, from janitor to principal, librarians, cleaning staff and teachers.

The two schools with many students from homes with low SES focused on information flow and communication between all actors involved. The complexity in these schools was overwhelming as many students needed individual attention and follow-up. As students’ needs varied from day to day, the work was continuously organized and reorganized. The two schools had established specialized teams “around” students *and* teachers, to care for students’ need and to allow the teachers time to teach. Specialized teams assisted students with additional training in reading, writing and math. Other teams were responsible for the learning environment or special education. Ideally, in Norway, all students are taught in class and therefore special educators come to the classroom instead of taking students out.

District level representatives and the school leaders at the six schools in the three profiles where schools contributed to students’ learning, collaborated regularly, in a climate of trust and shared responsibility. At the two schools with low contribution to students’ learning the last 5 years, dialogs between district level representatives and principals were more formal, focused on intentions and what ought to be done. Rhetoric of district level representatives indicated hopes that better alignment between district level documents and the schools’ documents could improve teachers’ practice and students’ learning outcomes.

The expert group concluded that local administrators must strengthen their educational knowledge, improve their understanding of schools, and use this to support struggling schools.

The quest for simplicity—human and social capital

While educational institutions are overwhelmingly complex, too often, policies aim at reducing the complexity by treating education as a series of simple cause-effect-activities. Policies often assume that schools need advice on what works, summed up by Berends (2004) as: the school effects research (1960–1970) effective schools research (1970–1980), and standards-based reform (1980–1990). Underlying such policy-initiatives, argued Ingersoll and Collins (2017), is a “teacher-deficit” assumption where the primary source of low-quality teaching in schools lies in various deficits in teachers, their ability, commitment, or effort. The best way to fix schools, is therefore to fix these deficits through increased external regulations, incentives, and sanctions.

This reasoning was central to neoliberal policies that emerged in the US under the presidency of Ronald Reagan and in the UK under Prime Minister Margaret Thatcher. Etzioni (1988) described the neoliberal paradigm as utilitarian, rationalist, and individualist. It assumes that individuals seek to maximize their utility, rationally choosing the best means to serve their goals. He suggested an alternative paradigm of *codetermination*, encompassing factors that form society and personality as well as rational decision-making. As individuals act within social contexts, social groups are not aggregates of individuals but have structures of their own, Etzioni argued. To explain neoliberal policy problems, Michael Walzer (2007) used the term *neoliberal fallacy*. While liberalism had contributed to allowing people to live within autonomous institutions with institutional integrity, neoliberal policies separated people: “people are not liberated when separated from their fellow beings. Lines encircle churches, schools, markets and families—not you and me” (Walzer, 2007, p. 63). According to Dewey (1915, 40), the primary waste in education is that of human life—all waste is due to isolation, which is a result of how schools are organized.

The OECD understands human capital as individual knowledge, skills, competencies, and attributes embodied in individuals that facilitate the creation of personal, social, and economic well-being (Keeley, 2007). They see human capital as critical to sustainability, productivity, and the current and future economic health of a country. Having linked human capital and productivity, Fraumeni (2012) concluded that while labor productivity can be measured, human capital productivity is neither easily nor reliably measured.

Coleman (1988) argued that while sociologists assume that actors act in social contexts of norms and rules that affects their actions, economists assume that people act freely and independently, have individual goals, and seek to maximize their return on investment. He therefore suggested to see social and human capital as entangled. Individual and goal rational action can be studied in a social context which makes it possible to explain the development of social structures that schools must establish and maintain. Coleman (1988) distinguished between three forms of social capital, (1) obligations and expectations, (2) information channels and (3) social norms. Having analyzed large datasets on school dropout, he concluded that the lack of social capital explains dropout. Social capital is embodied in the relations among people, a resource that showed evidence of considerable value in reducing the probability of dropping out of high school.

Powers et al. (2016) argued that policymakers had neglected the Coleman report’s fundamental insights about the relationship between poverty and student achievement by emphasizing measurement; human capital theory; and the use of the White, middle-

class male student as the implicit norm against which all other students were assessed and ranked. They labeled the systematic denial of class-based inequalities in shaping individuals' and groups' life chances *willful ignorance*.

Researchers have studied social capital as a resource. For instance, Spengler et al. (2015) assumed that social-emotional skills students learn in school, might help them succeed later in life. They conducted a longitudinal study spanning 40 years (1968 and 2008) to examine how student characteristics and behaviors in late childhood (age 12) predicted career success in adulthood. Having controlled for home background and intelligence, they found that student personality-related characteristics and behaviors played significant roles in important life outcomes, over and above socioeconomic factors and cognitive abilities. Being successful, they argued, is more than "just" having good cognitive resources and coming from a socially advantaged family. Therefore, educational systems should pay more attention to social-emotional skills. Merritt and Buboltz (2015) found that socioeconomic status (SES) was significantly related to students' self-efficacy, and parental influence was a significant predictor of academic self-efficacy.

If we perceive education as preparation for life instead of comparing schools to firms, education should compensate for what groups of students do *not* get from their family or neighborhood, instead of stressing their cognitive skills to increase the schools' test results.

What can be expected of teachers, given their working conditions?

Ingersoll and Collins (2017) argued that the teacher accountability perspective involves a flawed problem diagnosis. The simple logic is that when teachers are not held accountable, they simply do what they want behind closed classroom doors, with low-quality performance as predictable result. This logic, however, overlooks that how schools are managed and organized, influence teacher quality. Poorly run schools can make otherwise excellent teachers not so excellent.

Based on data from PISA (2012), Ingersoll and Collins (2017) showed that while the US education system is relatively decentralized, schools are not. While 26% of principals reported to have high power over curriculum in the 1990s, the number was 49% in 2012. Teachers are delegated much responsibility but have little real power. For most decisions, they lie at the bottom of the hierarchy. Principals decide teachers' course assignments, courses, and grade levels they teach. Teachers can be assigned to teach subjects which do not match their fields of preparation, they have no control over decisions regarding school curricula, limited control over the school's discipline policy, little say over what kind of student ability grouping the school has and which students are placed into which tracks. Teachers have little influence over the assignment of students to their courses and rarely the power to remove disruptive students from their classrooms. Ingersoll & Collins refer to Lortie (1975), who described the relationship between teacher and student as one of "dual captivity"; teachers are public servants who cannot choose to *not* serve their clients. Their clients are recipients of a public service and cannot choose to *not* be served. This stands in sharp contrast to traditional professions, such as lawyers, psychologists, or physicians, who often have a substantial degree of choice over whom they serve and may have the option to not work with certain clients.

While teachers are delegated the responsibility for implementing decisions within their classrooms, they are not typically part of the school management, nor are they the workers, but responsible for the workers— their students.

To sum up, the article started with politicians' concern about the strong relationship between students' family background and their learning outcomes. Since the Coleman-report, questions of the school's contribution to students' learning have been high on the agenda. Accountability reforms, based on a deficit perspective, aimed at pressuring teachers and schools to better achievement. Economists launched the statistical measure *education production function*, that supposedly, would show policymakers where their investments would yield the largest profits. Teacher quality was equated with largest possible increase in students' results. The understanding of schools as factories of human capital, i.e., that the main product produced by the school is individual cognitive skills that can be tested, measured, and compared at an aggregate level to indicate nations' relative competitive advantage, has narrowed the school's broader mission and frustrated teachers. Few have interrogated into the relationship between what is expected of teachers and their room for maneuver in implementing decisions. Ingersoll and Collins (2017) showed that teachers' work is constrained by larger national, district- and school-wide decisions, over which they have little influence. Old-fashioned neoliberal ideas about learning—back to basics, rote learning, drilling, and testing of skills contributed to de-professionalizing teachers, as they were not only told *what* to teach, but also *how*.

A more intelligent accountability

If policymakers cannot trust schools, teachers, and educational researchers, then who should they trust? The chapter has shown that over the last decades, many policymakers have trusted economists as educational experts. They have invested their trust, not only in the economists' equations, but also in their understanding of education, what matters in education and what is quality teaching. The economists' black-box approach and the idea that students' learning outcomes can be compared to firms' return on investments has expected schools to invest in human capital to "produce" gains in students' learning outcome. Old-fashioned policy-ideas about how we learn has favored educational practices that John Dewey deemed outdated more than a century ago (Dewey, 1915). Cognitive psychologists (Sloman and Fernbach, 2017), argued that individual intelligence is overrated, as human intelligence resides not in individual brains but in the collective mind. What goes on between our ears ultimately depends on what goes on elsewhere, and we therefore learn best when we collaborate. Some of the best learning techniques at every level of education is to have students

learning as a team. While this is not new to educational researchers, the insight is not implemented in classrooms as widely as it could be. Education is a complex field that suffers under single-factor solutions, and policymakers should therefore consult research from various fields.

O'Neill (2018) describe trust as valuable only when directed to agents and activities that are trustworthy. Having studied the work of 43 teachers and school- and district-leaders, Butler et al. (2015) concluded that most participants experienced increased efficacy when they engaged in collaborative inquiry. They ask if approaches that assess students' performance using large-scale, standardized tests and then mandate practices and monitor improvement on that basis fail to recognize the knowledge and expertise of educators, underestimate the importance of adapting practices to meet local needs, and undermine teachers' morale and investment in innovation. Based on findings from the Norwegian expert group, it can be added that these policies also neglect the importance of knowledgeable school leaders who organize for learning.

Ingersoll and Collins (2017) found substantial variation among schools in the degree of teacher control. Schools where teachers have more control over key school-wide and classroom decisions had fewer problems with student misbehavior, more collegiality and cooperation among teachers and administrators and higher teacher retainment. They also found a strong relationship between the average amount of teacher influence over discipline decisions and the likelihood that teachers stay in, or voluntarily depart from, their schools. Too much organizational control may deny teachers the very control and flexibility they need to do the job effectively and undermine their motivation. The variable that stood out in their study was how much autonomy teachers were allowed in their own classrooms over key issues such as selecting textbooks and other instructional materials, selecting content, topics, and skills to be taught, selecting teaching techniques, evaluating, and grading students, determining the amount of homework to be assigned and disciplining students. They conclude that at the crux of successful teaching is the level of control and power teachers have on issues for which they are responsible. This aligns with findings from the Norwegian expert group (Lillejord et al., 2021). In schools with a substantial contribution to students' learning, the principals knew how to utilize and strengthen teachers' educational knowledge. Teachers were empowered to lead the schools' professional learning communities and continuously reported suggestions for improvement to the school leaders. Swift information flow, organization for the purpose of learning, the combination of professional knowledge and administrative capabilities (O'Day, 2002) enabled these schools to organize robust social learning units where learning was both individual *and* social. These school leaders adhered to the three forms of social capital identified by Coleman (1988): obligations and expectations were systemic; information channels were effectively used, and social norms were clearly communicated, adhered to and followed up. Shain (2016) argued that we cannot expect that schools alone can address the impact of wider social inequalities, certainly not without significant investment.

Conclusion

A question raised in this chapter is if accountability reforms created more problems than they solved because they ignored the complexity of schools. When Onora O'Neill (2013) called for a more intelligent accountability, she used the word *intelligible*. This chapter contributes to the debate waging over how to establish frameworks that empower all stakeholders to exercise responsibility in an intelligent accountability system. If teachers are to improve their work, they must understand what they are being held accountable for, they must have the necessary authority, be able to control their professional working conditions and have leadership support. Elliott (1994) argued that the rationale for involving teachers as researchers of their own practice is connected to an aspiration to give them control over what is to count as knowledge about practice. Instead of applying knowledge generated by outsiders, teachers should generate their own professional knowledge. Aggregated data is an abstract form of knowledge with low explanatory power as the data is not the evidence, but the evidence is *in* the data (Ströing, 2018) and needs interpretation to be relevant for teachers' context. In trusting educational systems, all stakeholders are reciprocally responsible to one another, students, and the public to fulfill their joint responsibilities for educational outcomes. The case used in this chapter revealed that schools that contribute to students' learning have leaders—at school and district level—who understand that abstract, second order data must be translated to the first-order work of teachers. As accountability reforms have lost some of their momentum, the search for new and better policies continues. This chapter has suggested a strengthening of the teaching profession and their leaders as an obvious next step. Combined with strengthening the sectors and politicians' educational knowledge (Brezinka, 2012) the education sector can be better prepared for future attempts on a hostile take-over.

Glossary¹

Assessment The process of collecting data to document or measure student knowledge, skills, or dispositions. Testing is the most common formal means of assessment

Educational Accountability The concept of holding schools, administrators, teachers, and/or students responsible for students’ academic performance. Accountability policies vary across time and across jurisdictions in the types of school and student data that are used and whether rewards or sanctions are attached to performance. Most forms of educational accountability include student standardized achievement test scores as a key element and report the information publicly

High-Stakes Tests Assessments that carry serious consequences for students or for educators. Their outcomes determine such important things as promotion to the next grade or graduation or may be used to administer rewards or sanctions to schools or teachers. Even when there are no official rewards or punishments attached, reporting results publicly can have high stakes for teachers

Large-Scale Assessment Standardized tests and other forms of assessment designed to be administered to large numbers of students and to provide information on a standardized scale

Matrix Sampling An assessment administration method by which a large set of test items is organized into a number of relatively short test forms, each of which is randomly assigned to a subsample of test-takers, thereby avoiding the need to administer all items to all examinees

Program Evaluation Involves the systematic collection and analysis of data to determine the effectiveness of educational projects, programs, or policies. The use of assessment data to evaluate programs is distinguished from the use of assessment data to make instructional decisions about individual students. Program level analysis may entail disaggregating total school performance to check on program effectiveness for important subgroups or examining curricular strengths and weaknesses, as when students excel in basic skills but perform relatively less well on tasks requiring critical thinking

Standardized Test Tests that are administered and scored under uniform conditions for all students. Standardization ensures comparability of scores across individuals

Standards-Based Reform An approach to education reform that sets standards of performance in academic subject areas as a means to improve the substance of school curricula and increase the motivation and effort of students, teachers, and school systems and thereby improve student achievement. The reform assumes high standards for all students and has two

¹Definitions for terms associated with Standards Based Reform are adapted from McDonnell, L. M., McLaughlin, M. J., and Morison, P. (eds.). (1997). *Educating one and all: students with disabilities and standards-based reform*. Washington, D. C.: National Academy Press. And from McLaughlin, M. W., and Shepard, L. A. (1995). *Improving education through standards-based reform*. Stanford, CA: The National Academy of Education.

components challenging standards that set out what students should know and be able to do, and an accompanying agenda for educational equity

Introduction

When used well, “large-scale standardized assessments” provide educational stakeholders with valuable information about schooling while having a limited impact on the everyday operation of schools. Policymakers, for example, can use large-scale assessment to track trends in achievement and identify effective educational programs. When used in this way, assessment can be a tool for improving equity within and across schools. When misused or used poorly—for example, as a tool for punishing under-resourced schools—assessments can harm students by misdirecting the focus of school administrators, distorting how practitioners teach, and narrowing the purpose of education to performance on standardized tests. When used in this way, large-scale assessment can widen “opportunity gaps” by encouraging repetitive drill and practice for low-performing students and further disadvantaging schools serving students with the greatest needs. This entry examines how large-scale assessment has been used in educational policy over time, focusing on both the uses and misuses of assessment data.

The first section summarizes the history of assessment and accountability in the United States. The earliest uses of achievement and IQ tests in the mid-19th and early 20th centuries were for local program evaluation and to track students by ability. The role of achievement testing then shifted in the 1960s and 1970s to the relatively low-key beginnings of accountability, with Title 1 of the Elementary and Secondary Education Act (ESEA), and informational data collection for policymakers with the creation of the National Assessment of Educational Progress (NAEP) in 1969. The role of assessment in the United States evolved further during the 1980s because of complaints of educational stagnation and fear of “falling behind” economic competitors. During this time, assessment changed from a tool for program evaluation and public information to a lever for applying pressure to “failing” schools and school districts. Within this latter period, the role assessment played in policy is described, with particular attention to the “theories of action” informing its use, and the effect of this approach on the delivery of instruction and student academic outcomes on standardized tests.

The second section describes the use of assessment and accountability across and within international contexts. The use of large-scale international assessments such as The Program for International Student Assessment (PISA) and the Progress in International Reading Literacy Study (PIRLS) is presented first, considering the motivation for administering these assessments and the potential pitfalls when interpreting results. Then, as examples of large-scale national educational assessment systems across three continents, brief descriptions are given of the assessment systems and data use in Chile, Norway, and Singapore.

The use and misuse of assessment in the United States

Although standardized measures of academic achievement are used throughout the world, a large portion of the research on the use (and misuse) of large-scale assessment for accountability purposes has focused on the United States. This section examines the role of assessment in US K-12 educational policy as it shifted from 1840 to the present.

Assessment in the 1840s–1930s—program evaluation and ability tracking

The use of achievement tests in the United States began in the mid-19th century. Horace Mann, considered one of the founders of public education and the common school movement, sought to use evidence from student examinations to evaluate school programs and identify effective practices. Known for his vision of a universal common school, Mann saw value in creating common schools that could be scaled across contexts. Assessment offered Mann a tool for realizing that vision. To this end, Mann encouraged schools to adopt writing exams that could be used to inform state policymakers and inform student placement. Beginning in 1908, roughly 60 years after Mann’s initial push for using assessments in public schools, Edward Thorndike and other early experts in educational measurement began to design hundreds of achievement tests that could be used for educational program evaluation (Shepard, 2008).

In the same year, Henry Goddard published his version of the “The Binet and Simon Tests of Intellectual Capacity.” By 1913, the IQ test, as it would come to be known, was in use in public schools. At the time, the common belief about the intelligence quotient was that it could accurately measure a student’s inherited intellectual ability and capacity to learn. The promises of scientific measurement seemingly arrived just in time to address problems arising from a rapid expansion in both total enrollment in public schools and the diversity of students enrolling. These enrollment and diversity pressures, resulting from greater accessibility to high schools and an influx of immigrants from Europe in the years between 1880 and 1920, posed a challenge for policymakers—how to expand the common school while maintaining the vision outlined by Horace Mann for the “one best system.”

Policymakers would eventually adopt a system known as a social efficiency approach – a public education system where schools offer differentiated instruction (i.e., tracks) within schools ostensibly to account for variation in student capabilities (Tyack, 1974).

While there were some critics of IQ testing from the beginning, full-throated objections and scientific reexamination did not occur until the civil rights movement of the 1960s and 70s. Belatedly, it was recognized, at least among researchers, that assessment results are an indication of the learning opportunities an individual has received to that point, not a measure of an individual's innate ability (National Research Council, 1982). Thus, a system relying on assessment results for student placement cemented within schools the economic inequality and cultural, racial, and language discrimination that existed outside of schools.

This entry focuses primarily on the use of large-scale assessment data for policy and program evaluation purposes. Nonetheless, the legacy of IQ testing for individual student placement is worth noting because the implication that some groups of students are less capable than others continues to influence public discourse about achievement test results and the actions of some educators. For example, a recent consensus report on learning research from the National Academies of Sciences, Engineering, and Medicine (2018) found it necessary still to amass research evidence arguing against a “deficit” model of cultural difference.

Assessment in the 1960s–1970s—the passage of ESEA and the emergence of NAEP

The passage of ESEA and requirement of assessment in title 1 schools

The passage of the Elementary and Secondary Education (ESEA) of 1965 shifted the landscape of testing policy in the United States. Title 1 of ESEA provided federal dollars to schools serving students in poverty. In return, policymakers mandated that schools that accepted the federal monies provide evidence that the money was being used effectively to help economically disadvantaged students. The mandate marked a shift in the management approach of policymakers and the role of assessment within that approach (Resnick, 1980). The assessments tied to the first ESEA remained low stakes, however. Moreover, the desire to prevent the encroachment of the federal government into local practices meant that assessment remained “chaotically diverse,” leaving little policymakers could use the assessments for beyond local evaluation (Cronbach et al., 1980, p. 33).

The creation of NAEP

Because the various standardized achievement tests used for Title I evaluation offered little information that could be used to report on the nation as a whole or to monitor progress over time, policymakers sought a very different kind of achievement test (Lehmann, 2004). In 1969, efforts of Ralph Tyler and others culminated in the creation of the National Assessment of Educational Progress as a data collection tool analogous to the US census. NAEP would provide information to policymakers on the academic standing of students, nationally and by region, in different subject areas at key age levels. The program was not designed to apply pressure—specifically, there were not to be rewards and punishments attached to performance on the test.

Further, NAEP was designed to be minimally intrusive in schools. The assessment was administered using matrix sampling, a technique designed so that multiple students take different parts of the test. Sampling of students avoids the problem of requiring every student in a state, district, or school to take the total test, thus, lowering the cost of testing. Sampling of test content across sampled students also allows much greater coverage of content domains without undue time demands on participating students, thus ensuring a much higher quality test.

Over time, policymakers have sought to shift the relevance and usefulness of NAEP. For example, policymakers sought changes to NAEP that made it possible to compare results across states. At the same time, the National Assessment Governing Board (NAGB), instituted by Congress in 1988 to oversee NAEP, decided to change the format for reporting NAEP results to make them more digestible for public consumption. This included setting subjectively determined “achievement levels” indicating basic, proficient, and advanced performance. While varying across grades and subject areas, the proficiency threshold for “what students should know” was generally set quite high, at roughly the 75th percentile, which led to more worrisome results than when district administered tests norm-referenced tests had claimed the majority of students to be above average. These changes to NAEP marked a shift that coincided with increased political interest in the performance of schools and a desire to focus public attention on inadequacies in the quality of American schools. While the move did not involve direct accountability sanctions, it again signaled a shift in general beliefs about how assessment could and should be used in educational policy.

Assessment in the 1980s–2015s—standards-based reform (SBR), incentive theory, & NCLB

A shift to “excellence,” SBR, and incentive theory

Early in the 1980s, politicians called for improvements to the educational system, fearful that an apparent test score decline (on the SAT, not NAEP) threatened to diminish the US's economic and political hegemony in the world. This sentiment—which was known as the “excellence movement”—is perhaps best captured by the publication of the 1983 U.S. Department of Education's report entitled *A Nation at Risk*. The report, commissioned by the Reagan administration, called for a reinvestment in public education and a greater role for assessment and accountability in K-12 public schools. Unfortunately, the movement focused primarily on tests of basic skills, resulting in a watered-down curriculum (Resnick and Resnick, 1992).

It was not until the early 1990s that policymakers sought new ideas about what large-scale assessments should measure and how they should be used as part of accountability systems. Educational researchers and policymakers eventually adopted the theory of action known as systemic reform or standards-based reform (SBR) (Smith and O'Day, 1991; Resnick and Resnick, 1992). SBR holds that clear and visible standards—i.e., those identifying what students should know and be able to do—when accompanied with high-quality teacher training, instructional materials, and improved assessment practices, could enable students to reach higher levels of performance by prompting schools to organize themselves around best practices and high expectations. As part of SBR,

assessments would be used to track student performance toward those high expectations. The theory stopped short of mandating a national curriculum or attaching sanctions when schools failed to meet expectations.

Simultaneously, however, a different group of policy leaders and researchers, working more from the perspective of economic theory than learning research, were advocating for the use of incentives to motivate educational change in US K-12 public schools (Elmore and Rothman, 1999). When applied to education, incentive theory holds that policymakers should tie school performance on academic standards to rewards and punishments. The threat of sanctions, they argued, would motivate schools to identify best practices that more effectively served students. The incentives approach was in contrast to the capacity building approach encouraged by advocates of standards-based reform. According to the incentives view, capacity building—e.g., teacher training, improved curricula, and better assessments—would be accomplished indirectly by encouraging schools to pursue those resources through their own initiative. Incentive theory, still named SBR, gained national attention because of the perceived success of such reforms in places like Texas—otherwise known as the “Texas Miracle.” Years later, studies comparing Texas test scores on state standardized tests to Texas scores on NAEP would conclude that much of the “success” was the result of test-score inflation, not real academic progress (Klein et al., 2000).

The passage of No Child Left Behind (NCLB)

No Child Left Behind, the 2002 reauthorization of ESEA, intensified the strictures of incentive theory in federal law. NCLB continued the idea of assessments aligned to challenging content and performance standards, but instead of requiring tests once at each level of school (elementary, middle, and high school), reading and math tests were mandated every year from grades 3–8. In addition, state policymakers were required to establish targets for adequate yearly progress and to report disaggregated assessment data by race and socioeconomic status. NCLB, thereby, provided state officials with a tool to punish “underperforming” schools.

Specifically, the use of assessment to hold schools accountable was intended to impact multiple parts of the K-12 educational system in the United States—i.e., it would improve system alignment, increase test performance, close achievement gaps, enable school turnaround for the worst performing schools, and improve educational outcomes for students with disabilities. While there is evidence that high-stakes accountability made a difference in some of these areas, the results were not as substantial as some would have hoped. A review of studies published by the National Academies of Sciences, Engineering, and Medicine, for example, found that the effect of incentives and test-based accountability on student achievement was small (National Research Council, 2011), about 0.08 of a standard deviation, on average, with most of the improvements being concentrated in elementary mathematics.

Despite these small positive effects, however, many, perhaps a majority of, educational researchers consider the use of assessment in high-stakes accountability policy to be an overall net failure because of the negative effects high-stakes assessment has had on teaching and learning. Prior to the implementation of NCLB, experts in the field of measurement had cautioned that a narrow use of assessment to punish schools would result in the corruption of measures and would be a distraction for policymakers, turning attention away from the work required to build local capacity for schools to successfully serve students. They were right—NCLB encouraged school administrators and teachers to focus most of their attention on standardized tests, resulting in test-score inflation and curriculum narrowing, stress and de-professionalization of teaching, and deficit views of students and dead-end student placements. A meta-synthesis of 49 qualitative studies, for example, found only rare exceptions to the familiar pattern of curricula narrowed to tested subjects, fragmentation of subject matter knowledge into test-related pieces, and increased use of teacher-centered pedagogies (Au, 2007). The fact of test-score inflation is such a well-recognized problem that all of the best studies, of NCLB and accountability effects reported above, rely on independent NAEP results rather than gains on likely-inflated state test results.

While the blunt use of large-scale assessment to sanction schools was seemingly reduced in the 2015 reauthorization of ESEA—the Every Student Succeeds Act signed by President Obama—there was no reduction in the amount of testing required. Thus, the federal approach to educational policymaking continues to rely on large-scale assessment as a tool for educational accountability.

The use of assessment across and within international contexts

This section reviews the use of large-scale standardized assessment across and within international contexts. The first part of the section focuses on the use of large-scale international assessments, considering specifically the motivation for using those assessments and the potential pitfalls in interpreting testing outcomes. The second part examines the use of large-scale assessment in educational systems in Chile, Norway, and Singapore.

The use of assessment across international contexts

Around the time assessment began to grow in the United States in response to the passage of the first ESEA, the United States, along with other high- and upper middle-income countries, began exploring the possibility of conducting large-scale standardized assessments across international contexts (Lockheed et al., 2015). In 1960, the first meeting for the International Association for the Evaluation of Educational Achievement Pilot Study (IEA) was held. The convening included representatives from Belgium, England,

Germany, France, Finland, Israel, Poland, Scotland, Sweden, Switzerland, Yugoslavia, and the United States. The conclusion from initial pilot studies was that large-scale international assessments could be conducted despite concerns about “translation and administration” across contexts. Over time, participation in international assessments grew, as did the number of international assessments in which countries could participate. Among these are the Trends in International Mathematics and Science Study (TIMSS), The Program for International Student Assessment (PISA), and the Progress in International Reading Literacy Study (PIRLS) (see [Scherer and Nilsen, 2022](#), for more discussion of international assessments).

Arising at the same time as increasing economic globalization and economic development, international assessments such as the TIMSS and PISA have served as indicators of the effectiveness of international educational systems. Much like the use of measures of economic development—such as, the growth rate of a country’s Gross Domestic Product (GDP)—international assessments offer policymakers across the globe a tool to make international comparisons and track improvements in educational systems.

However, making comparisons across international contexts can be challenging. For example, a report published by the Economic Policy Institute argues, among other things, that it can be challenging for test-makers and administrators to create truly representative national samples and select which topics will be included in tests ([Carnoy and Rothstein, 2018](#)). The authors point out that in 2009, PISA oversampled low-income US students attending schools with similarly economically disadvantaged students. They argue this artificially lowered US results. With respect to subjects tested, the authors note that on the TIMSS, the United States and Finland performed about the same on mathematics. The underlying results, however, showed that the United States performed better in Algebra but worse in number properties (e.g., fractions). Algebra is weighted less on the TIMSS, however. Caution should therefore be practiced when interpreting the results of international assessments to make international comparisons.

Assessment within international contexts

Much like the globalization of economic policies experienced throughout the 1990s and 2000s, educational “policy borrowing” has resulted in the spread of policies and practices between the United States and other regions of the world ([Lingard and Lewis, 2016](#)). Large-scale assessment is an example of a tool policymakers have adopted across international contexts. This section examines how assessment is used in Chile, Norway, and Singapore.

Chile

In the United States, high-stakes accountability policy developed over time in a confluence with school choice policy. That is, school choice advocates found assessment to be a useful tool to rank and grade schools as part of a marketized system where parents could use test data to choose schools. In Chile, high-stakes accountability policy came after the establishment of school choice. In the 1970s, Chile underwent an economic revolution during the dictatorship of Augusto Pinochet. Under Pinochet, leaders in Chile created a school voucher system to facilitate school choice ([Weinstein et al., 2016](#)).

Chile began using national large-scale assessments in 1988. The system—called the Sistema Nacional de Evaluación de Calidad de la Educación (SIMCE—The National System for Evaluating the Quality of Education)—requires that tests be administered to students in fourth, eighth, and tenth grade. Initially, the system was low-to moderate-stakes. SIMCE results were not made public until 1995, when Chile’s Ministry of Education changed its policy to create a school ranking system that would, in theory, help families make decisions about school choice. Between 2003 through 2013, Chile used the system to rate schools as “advanced,” “intermediate,” or “inadequate.” The logic behind the ratings was that “pressure” on schools would be applied by threats to student enrollment—i.e., parents could use the information offered by assessments and the power of choice offered through a school voucher to move their children to a different school.

Chile’s leaders quickly realized that its system of public education had resulted in large gaps in school performance with the gaps largely determined by socioeconomic status. These gaps were caused in part by the socioeconomic segregation that had developed as a result of parental choice ([Hsieh and Urquiola, 2006](#)). To address the problem, in 2008 Chile offered families from economically disadvantaged backgrounds a “preferential student voucher” (subvención escolar preferencial (SEP)). In Chile, all children can receive a voucher, but the SEP program offers vulnerable students a voucher worth more money. In 2015, the law reached the lowest 60% of the country’s income distribution ([Elacqua et al., 2019](#)).

Along with the new monies, however, Chile required schools that accepted the SEP voucher to accept a harsher accountability system. Schools that agreed to receive the funds had to sign a four-year education improvement plan (Plan de Mejoramiento Educativo) that included a commitment to raise the school’s SIMCE scores, innovate, reduce dropout and grade repetition, improve working conditions, and increase parental involvement. Much of the assessment of schools (70%) was determined by SIMCE scores. If the school failed, it could be labeled “in recovery,” have its budget cut, be taken over, and/or be closed.

Since the implementation of the policy, student scores on national assessments have improved, although it remains difficult to estimate how much of the increase was caused by the implementation of the SEP. Recent studies have found that the policy did have some benefit by (1) providing more funding to schools already enrolling a large number of economically disadvantaged students and (2) increasing the number of private schools participating in the program. Qualitative studies of changes in school behavior, however, have raised concerns over narrowing instruction to focus on test performance and arrangements for low-performing students to be absent for the test. Such findings have raised questions about inflation in test performance or whether additional funds tied to school sanctions determined by assessments are resulting in meaningful academic improvement for Chile’s economically disadvantaged students ([Elacqua et al., 2019](#)).

Norway

While the use of large-scale assessment in Norway has changed in recent decades with policymakers placing a greater emphasis on the collection of student academic outcome data through assessment, Norway's approach remains light relative to the use of assessment data in educational systems in other countries (Skedsmo and Mausesthaugen, 2016). This is due in part to the emphasis on trust and professionalism Norway places in its teachers (Lillejord, 2022).

Norway began using assessment as part of a "school-based evaluation" system in the 1990s. Much like the United States, however, the general public in Norway was motivated to increase the role of assessment for information about student outcomes after the country's educational system was perceived to have underperformed relative to international economic competitors. In 2001, Norway faced "PISA shock," as reported in national media, when its system ranked below average in math and science and underperformed in literacy as well. In response, the country sought to increase pressure on schools by publishing the results of assessments to the public. The country also implemented significant curricular reforms (Hopfenbeck et al., 2013; Lillejord, 2022).

In 2002 and 2004, the Government of Norway published two green papers encouraging more attention to individual learning outcomes and improved instructional practices. Those two papers provided the framework for what would become Norway's National Quality Assessment System (NQAS) and national curriculum (the Knowledge Promotion Reform), which emphasizes basic skills in reading, writing, oral communication, digital literacy and numeracy. Underlying the implementation of NQAS were calls for more data and information about school and individual student performance.

NQAS uses a combination of outcomes on national tests, international assessments (i.e., PISA, TIMSS, and PIRLS), the "school-leaving" examination (exit exam taken at the end of secondary school, the "Craft Certificate" (the certificate for qualifying for vocational education), and individual student grades. In Norway, municipalities use performance on NQAS to publish school results and rank schools. Not at all municipalities, however, publish school rankings. Moreover, Norway does not attach any government-regulated sanctions to school performance on NQAS. Again, this is due in part to the trust placed in school leaders and teachers as capable professionals pursuing the best interest of students (Lillejord, 2022).

Internationally, Norway regularly places above the average in student performance on assessments across grade levels and subject areas. The country is considered to have one of the more efficient and effective educational systems in the world. Despite this performance when viewed externally, educational stakeholders within Norway continue to raise concerns about how the use of national assessments to publicly pressure schools might distort behavior and motivation in classrooms.

Singapore

The Singaporean system of education makes use of assessment in similar ways to each of the countries reviewed above. As in other countries, the shift over time in educational policy and in the use of assessment has been spurred by the perception of educational failure and a greater emphasis on connecting educational outcomes to economic outcomes. In the 1980s, for example, Singapore sought to incorporate into its educational system the practices of successful businesses and non-profit organizations. The shift to greater educational accountability was motivated in part by the 1985 global economic crisis. This movement was further spurred by the economic collapse in Singapore in 1995; and recent changes in school design and goals have reflected shifts in the skills Singapore believes students will need to remain competitive on the global stage. Currently, the state uses assessment as part of a three-pronged system of accountability, which includes Singapore's school ranking system, the School Excellence Model (SEM), and the School Awards system (Tee Ng, 2010).

Singapore introduced its school ranking system in 1992. The logic behind the system was that competition would improve school performance. This presentation of school performance was not tied to sanctions or rewards like those used in the United States. Instead, Singapore's ranking system ranks schools based on three criteria: student performance on national exams, the "value-added-ness" of a school (i.e., the gain in test scores that can be attributed to a school), student performance on the National Physical Fitness Test, and the percentage of students in a school who are overweight. While school rankings were initially published to the public, Singapore eventually discontinued the practice to avoid an overemphasis on academic results (Loh and Hu, 2019). The state now provides school principals with a list of comparable schools, where comparability is determined by school-level student characteristics, such as student socioeconomic status, student ethnicity, and parental educational attainment.

The SEM was introduced in 2000. It requires that schools conduct a self-evaluation once a year, with a state evaluation occurring every five years. The SEM model rests on the assumption that schools are operated by "enablers" who produce "results." In the SEM model, "enablers" are judged on leadership, strategic planning, staff management, resources, and student-focused processes. Alternatively, "results" are judged by measuring administrative and operational outcomes, staff outcomes, partnership and society outcomes, and key performance outcomes, where "key performance" accounts for 30% of a school's total score and includes data from a school's performance on national assessments and learning outcomes.

The School Awards system, or the Masterplan of Awards (MoA), is part of Singapore's SEM system. It recognizes schools for their performance in several areas. For example, achievement awards are given to schools for the year's achievement; development awards are awarded for achievements in character development and national education; best practice awards are given to schools based on "enabler" outcome scores; sustained achievement Awards are given to schools for sustained performance in "results" outcomes. Singapore also gives out outstanding development awards for outstanding and sustained achievement in national education and character education and school distinction awards and school excellence awards that recognize exemplary school processes and practices and overall performance, respectively. Singapore reports the number and type of awards won by each school. It does not, however, report "failing" schools—or schools that perform poorly on the SEM measured outcomes. As an example of the criteria considered by the Singaporean Ministry of Education in determining an award, consider the characteristics used to describe three schools that

received “school excellence awards” and “best practice awards.” The schools St. Hilda’s Primary, Chung Cheng School (Main), and Dunman Secondary received these awards because they prepared students holistically—i.e., emotionally, physically, and cognitively, emphasized leadership in their curriculum, and tied learning to constant development aimed at fostering a global outlook and 21st century skills (Ministry of Education – Singapore, 2010).

Unlike the United States, Singapore does not attach sanctions to poor school performance. The system is designed to apply pressure through public scrutiny and centralized forms of government control. That is, the Singaporean system of education does not rely on local control as an aspect of governance. As a city and small country, there are not intermediate district or state levels of governance. All schools in the country are accountable to the Ministry of Education. Most schools in Singapore are public and most students attend public schools. Like Norway, Singapore also holds much greater control over the curriculum used in schools, giving it greater control over the alignment of curriculum, assessment, and expectations.

Singapore continues to be one of the top performers on international assessments. It regularly scores in the top five countries on PISA and TIMSS in various subject areas and across all grade levels. Singapore serves just over half a million students. For comparison, the United States serves close to 50 million students.

Conclusion

When used well, assessment offers valuable information that can support student learning. For example, state and national-level standardized assessments can offer information on the performance of individual schools and school districts and the effectiveness of educational programs and resources. However, when misused, assessment can diminish the educational opportunity of students by narrowing the curriculum and distorting the practices of teachers.

In the United States, large-scale assessments have shifted from tools for program evaluation and public information to levers for state policymakers to “pressure” schools into educational change. Although policymakers had hoped this approach would result in better academic outcomes for economically disadvantaged students and students from racial minority groups, the results have been underwhelming. The costs of the misuse of assessment, however, have been substantial. Since the passage of NCLB, for example, the focus on large scale standardized testing outcomes has crowded out policy discussions of more systemic changes to schools—such as the capacity building approaches that had been recommended by SBR, e.g., high-quality teacher professional development, instructional materials, and assessment.

Similarly, the role of international assessment has grown both within countries and across countries, albeit not at the pace and scope as in the United States. International large-scale assessments, like the PISA, PIRLS, and TIMSS, for example, have become popular metrics for assessing trends in the quality of educational systems around the world. And within countries, like Norway, Chile, and Singapore, large scale assessments have become a powerful lever for policymakers to track and pressure schools, although the variation in accountability policy approach remains significant.

Glossary

Adjustment A change made to an assessment item, form or condition to facilitate the needs of a student with disability. A change to the content demand of assessment may be termed accommodation.

Disability An impairment that affects a person's cognitive, physical or affective abilities that may be short term or long term.

Assessment The process of obtaining evidence of a person's learning or achievement.

Accountability The use of assessment evidence to make judgements, especially comparative judgements, about the effectiveness of an educational system, program or teaching.

Introduction

In this chapter we explore and extend our work on equity of assessment for students with disability in Australia (Cumming, 2008, 2012; Cumming and Dickson, 2007, 2013; Cumming et al., 2013; Dickson, 2003, 2012; Dickson and Cumming, 2018; Dickson et al., 2021; Rasooli et al., 2021). Over this time, we find there has been some crystallization of issues in the educational delivery of equitable assessments for students with disability but not necessarily clarity of procedures and processes for their implementation.

Three universally-accepted principles inform the education of children with disability. First, all children with disability have the right to education (UN Convention on the Rights of the Child, 1989; UN Convention on the Rights of Persons with Disabilities [CRPD], 2008; UNESCO, 1994). Second, such education should be "effective" (Salamanca Statement) to maximize opportunities and achievements for these students, with the expectation that policy and policy strategies will engage with a framework of "inclusive education" for as many students as possible, within inclusive education settings, and further creating more inclusive society (UNESCO, 1994). Third, students with disability have the same right as their peers without disability to have their achievement monitored to inform future instruction as well as to report progress (Cumming, 2012). A fourth principle, not so universal in implementation, is that students with disability have the right to participate in national and international monitoring of student achievements.

These principles have a strong basis in underlying philosophies of social justice and equity. In translation into conventions and policies, focus moves to equitable opportunities and removal of barriers and oppression (Rasooli et al., 2021; Sabbagh and Schmitt, 2016). Taking a human rights perspective, Rioux (2014) identified the responsibility of society to educate all students, including students with disability.

The responsibility of the school system is to develop and sustain a place of learning that enables every child to exercise her or his fundamental right to education and learning. It is about the right of children to an equal place in society (p. 135).

Increasingly, in policies to enact inclusive education, the categorization of students with disability has changed from reliance on a medical model that identifies a disability as a deficit in the person that can be diagnosed (medically) and labeled, to a social model of disability, whereby barriers to participation are created by society, and context, not the individual themselves. A more complex

model of disability that bridges the medical and social, the biopsychosocial model of disability, perceives barriers to participation as an interaction between the characteristics of the individual and the social context (World Health Organization, 2002).

From a social perspective, the idealized vision of education for students with disability is inclusive education without restrictions. Inclusive education developed philosophically as the opposite of exclusive education. Historically, since the introduction of public education for the masses, students with disability were educated separately from other students, in “special” education settings; many were not educated at all. In inclusive education, as many students with disability are educated within mainstream classrooms as possible. In the 21st century, this is interpreted as more than the mere presence of students with disability in a classroom; it is the provision of education that supports each student and seeks to remove restrictions and barriers to make the educational experience of these students as similar as possible to the experiences of their peers without disability.

Inclusive education requires an educational framework of policy and practice, including inclusive pedagogy (Florian and Black-Hawkins, 2011), and, as an integral component of education, inclusive assessment, identified in part as “a range of methods and strategies that aim to gather clear evidence about learners learning in non-academic areas as well as academic subjects” (European Agency for Special Needs and Inclusive Education [EASNIE], 2007). A common theme in international statements, policies and guidelines, as noted earlier in the Salamanca Statement, is to focus on optimal development and outcomes for students with disability. Therefore, by corollary, inclusive assessment practices that will enable students with disability to demonstrate their achievement optimally are essential. In keeping with changing models of disability, inclusive assessment is seen as a shift “from approaches that are used for most learners with something ‘additional’ or ‘different’” to address “deficit” needs of a student with disability, “to an approach that provides rich learning opportunities for everyone, so that they can all participate in classroom life” (Florian and Black-Hawkins, 2011, p. 216).

Inclusive education is often paired or discussed in terms of Universal Design of Learning (UDL), which originated from the development of inclusive building design to remove barriers that prevented accessibility for individuals with disability. Principles of UDL are intended to optimize access and provision for all through considering diverse and variable needs of individuals and providing, expressed most simply, “multiple means” of “engagement,” “representation” and “action and expression,” that is, for the last, to “differentiate the ways that students can express what they know” (CAST, 2021). Therefore UDL, and, more generally, inclusive assessment approaches, address “the design and use of fair and effective assessment methods and practices that enable all students to demonstrate to their full potential what they know, understand and can do” (Hockings, 2010, p. 34).

Internationally, in many countries, policies and frameworks for inclusive education for students with disability, and in some countries for inclusive assessment, are supported by legislation such as the introduction in the US of the *No Child Left Behind Act* (NCLB) (2002). Without elaborating on subsequent issues with this act for students with disability, its introduction was seen by educators in the US as significant at that time in recognizing that students with disability should be included in, not excluded from, national assessments to monitor student learning (McDonnell et al., 1997). Hence, the progress of these students was identified in law as important.

Examining social, educational and legal considerations of inclusive assessment: Australia as a case study

The Australian context¹ is similar to those of many other countries (Cumming, 2012). As a signatory to the many international conventions and policy statements about the rights of persons with disability and of children in general and in education, Australia has established education policy that endorses principles of inclusive education for students with disability (Australian Curriculum Assessment and Reporting Authority [ACARA], 2012; Cumming et al., 2013; Education Council, 2019). Statements of national priorities in Australian education, most recently the Alice Springs (Mparntwe) Education Declaration (Education Council, 2019), establish the goal that all students “at risk of educational disadvantage” should be able to reach their potential, including students with disability. “Equity” of opportunity is a priority to support their achievement and “achieve their highest educational outcomes” (p. 17). For students with disability, this can be seen as recognizing the individuality of each student and their learning needs, rather than categorizing students according to a medical definition of disability (Nisbet and Shaw, 2020).

Data and evidence of student learning and improvement are highlighted in the Mparntwe Declaration, both through national and international accountability assessment and school-level assessment that is “world-class,” including assessment “for,” “as” and “of” learning and assessment (Education Council, 2019, p. 15). Focus on assessment for learning has grown in the last two decades, seen as encompassing principles that make learning a key factor of assessment (Assessment Reform Group) (Broadfoot et al., 2002), and consequently making the student the center of learning, and assessment processes and goals. Such a central role is consistent with a social perspective of democracy that informs social justice views of inclusion (van Swet et al., 2011) as well as focusing on the experiences of the individual (Rasooli et al., 2021). Implicitly, such policies are intended to be enacted in practice at the system, school and individual classroom level.

¹A note: The Australian legal system is similar to many other systems in Western countries, emerging from the English common law system and involving both criminal and civil law. Unlike England but similar to the US, Australia does have a written Constitution which can also be the basis of legal challenges. However, unlike the US, Australia in general is not a litigious society, especially in education, with many challenges resolved through mediation or tribunals, rather than formal law courts. When Australian challenges in education reach the courts, they are frequently settled out of court, often to ensure no precedent is established (Cumming and Dickson, 2007). There is evidence, however, that legal challenges in education, and in education assessment, in Australia are increasing, especially in areas such as higher education which may have consequences for employment and where ambiguity exists about the role of students as consumers (Cumming, 2008; Pullin and Cumming, 2022).

Inclusive education policies are endorsed at state and territory level in Australia, with the intention to maximize success for all students with disability (see, e.g., [Education Queensland, 2021](#)), although we have found that practical guidance for teachers in how to provide such world-class assessment for learning, and especially for students with disability, is limited ([Cumming and van der Kleij, 2016](#); [van der Kleij et al., 2018](#)). These limits are reflected in the key issues in inclusive assessment that are universal that are discussed later.

As in other countries, Australia's inclusive education policies are reflected in and strengthened through legal frameworks that address potential discrimination against students with disability in education ([Dickson and Cumming, 2018](#); *Disability Discrimination Act 1992* (Cth)² [DDA]; *Disability Standards for Education 2005* ["Standards"]). Discrimination may be direct, treating a student less favorably because of their disability. Examples would be denying enrollment based on a disability, or denying a right to participate in an assessment because of a disability ([Dickson and Cumming, 2018](#)). It may also be indirect, requiring a student to comply with an unreasonable condition that they cannot meet because of a disability, and which causes them disadvantage. An example would be requiring a student with vision impairment to read the same printed format assessment as students without such an impairment ([Dickson and Cumming, 2018](#)). In Australian law, disability is defined broadly (*Disability Discrimination Act 1992* (Cth)), encompassing physical, cognitive, psychiatric, behavioral and sensory disabilities, including disability that is shortterm, ongoing and/or potential. The *Standards*, which draw on the DDA definition of disability, identify the requirements for education providers for equitable education for students with disability.

Two core principles are identified in the *Standards*. Students should be able to engage in their education "on the same basis" (§ 2.2) as students without disability and all aspects of their education should be "accessible" (§ 6.3). To provide such equal opportunity and accessibility, providers—system and school level—are to provide "adjustments," "a measure or action" that assists a student with disability (§ 3.3) with the proviso that such adjustments must be "reasonable" (§ 3.4). Reasonableness is to be determined by consideration of a student's needs, in consultation with the student and their parent or carer, about the student's disability and its intersection with their education (§ 3.5). The effect of adjustments on a student's ability to participate in courses or programs, the effect on others, costs and benefits of making an adjustment, and the "balance of interests of all parties affected" are also relevant to reasonableness. Provision of an adjustment should not impose unjustifiable "hardship" on the provider (§ 3.4 Note).

Assessment and certification requirements are identified as an area where adjustments to enable full participation should be made. Assessment requirements should be accessible for the student, with "assessment procedures ... adapted to enable the student to demonstrate the knowledge, skills or competencies being assessed" (§ 6.3). Again, consultation with the student or their parent or carer should identify whether an adjustment is necessary and whether an adjustment can be identified to achieve this aim (§ 6.2). Assessment adjustments must also be reasonable, and importantly,

a provider may continue to ensure the integrity of its courses or programs and assessment requirements and processes, so that those on whom it confers an award can present themselves as having the appropriate knowledge, experience and expertise implicit in the holding of that particular award.
(§ 3.4 Note).

Under law, the principles of inclusive education are to be met by adjustments to suit the needs of the student with disability. As such, delivering education "on the same basis" to students with disability may mean treating them differently, rather than the same, potentially a deficit model of disability. Moreover, in practice, adjustments are often determined through considerations from the medical model of disability, relying on diagnosis, often medical, and certification as evidence of disability. The extent to which adjustments should be provided are limited by perceptions of reasonableness and, for assessment, integrity. However, the underlying philosophy is to ensure that students with disability are consulted about and able to access full education. Students with disability are accorded rights to quality education that are not generalized to other students in Australia law.

Frameworks for inclusive assessment: social, education policy and practice, and legal

It is clear that different philosophies, policies and legislation create different frameworks for inclusive assessment for students with disability.

Social perspective

From the social perspective, inclusion is "aspirational in nature" ([Finkelstein et al., 2021](#), p. 737). The fullest social perspective would provide every student with disability with all educational opportunities they need to learn, and to demonstrate their learning, that

²Australian discrimination legislation exists at both federal ("Commonwealth") and state or territory levels. The state and territory acts (*Discrimination Act 1991* (ACT); *Anti-Discrimination Act 1977* (NSW); *Anti-Discrimination Act* (NT); *Anti-Discrimination Act 1991* (Qld); *Equal Opportunity Act 1984* (SA); *Anti-Discrimination Act 1988* (Tas); *Equal Opportunity Act 2010* (Vic); *Equal Opportunity Act 1984* (WA)) address a range of attributes on which discrimination may occur and specifically include disability or impairment. The federal act is specific to disability. The federal, state and territory acts are similar and do not cause conflict in application in courts and tribunals. The *Disability Standards for Education* are authorized by and subordinate to the *Disability Discrimination Act 1992* (Cth).

is, there would be no restrictive parameters. However, social perspectives of equity and fairness in assessment, in themselves, are not simple. The most recent edition of the *American Standards for educational and psychological testing* (American Educational Research Association et al., 2014) provides a chapter on fairness in testing, without defining the concept but noting that “fairness ... is an overriding, foundational concern” (p. 49). Social justice and fairness derive from social context (Nisbet and Shaw, 2020; Rasooli et al., 2021). Education systems in all countries rely on funding allocations, mostly public funding derived from taxation, for provision. Education funding is in competition with health funding, resource funding and social welfare provision, to name a few. Resources, both financial and human, are finite. When resources are finite, decisions have to be made about how to distribute these resources. Not only may education be perceived as a different priority in many countries, different decisions within education may prioritize different student groups or different outcomes (Deutsch, 1975). In terms of equity and fairness in social justice, one area where alternative considerations arise in assessment is whether the focus is on fair process or fair outcome (McArthur, 2016). These are complex issues for which there is no right or wrong answer, despite the sense that most countries are committed to inclusive education for students with disability, and, implicitly, inclusive assessment practices.

Education policy perspective

From an education policy perspective, policy expressions of social inclusion goals may also be aspirational, such as the first Australian national goal to “provide all young Australians with access to high-quality education that is inclusive and free from any form of discrimination” (Education Council, 2019, p. 5). However, given, as noted, that resource allocations may restrict inclusive education in practice, the goal of inclusive education may be more appropriately considered as ambitious. In most countries it is also seen as work-in-progress. For example, a policy document noted earlier marries social ambition with practical resource constraints, referring to the “next phase of reform as we continue our journey toward a more inclusive education system” while also noting “[transition] to a new resource allocation model for students with disability” (Education Queensland, 2021). Professional development of education personnel is seen as critical to developing inclusive education, although inclusive assessment is rarely mentioned in policies (see, e.g., Education Queensland, 2021), despite the recognized difficulty of changing teacher assessment practices to be more inclusive (Deneed and Boud, 2014; Offerdahl and Tomanek, 2011). Teacher preparation programs are expected to develop graduate teachers who are able to engage with students with disability (EASNIE, 2021), however, again, guidelines linked to such expectations are usually generic rather than explicitly focused on inclusive assessment (see, e.g., Australian Institute for Teaching and School Leadership, 2020).

Policy frameworks do not intentionally impose barriers on inclusive assessment. However, *from an educational practice perspective*, three parameters emerge that affect implementation. The first parameter, which is linked closely to the third, relates to teachers’ knowledge of how to practice inclusive assessment and the limitations on their willingness to engage with such assessment practice. As noted, practical guidance is still limited. The second parameter, which is not to be dismissed lightly, is the perspectives of students with disability themselves. These students may not wish to identify as having a disability, setting themselves apart from their peers (O’Rourke and Houghton, 2008; Woodgate et al., 2020). They may not perceive themselves as having a “legitimate” disability that would enable them to have considerations of assessment approaches in place, and, they themselves may also perceive that inclusive assessment practices may be “unfair” and create an advantage for them (Tomlinson and Moon, 2013).

The third parameter is the approach most frequently taken to inclusive assessment in practice, as identified in the Australian law, the provision of adjustments to mass assessments designed for the majority of students to make them suitable for students with disability. In the US such adjustments are referred to as accommodations or adaptations (AERA et al., 2014). The principle of an adjustment is that it makes changes to an assessment design to be accessible to a student with disability, based on their needs. Ideally, under UDL, assessments would be designed to suit all students so that adjustments or accommodations are not necessary. However, from the perspective of “critical realism” (Pawson, 2013), this is unlikely, given the need for due consideration of a multiplicity of factors: the disability of a student, the context and background of the student, the area being assessed, and the setting. In practice, this is difficult, especially for larger-scale tests. Differentiation of assessment design and modes becomes the critical focus in practice. Principles of UDL provide guidelines for diverse assessment development to reduce “noise” in assessment tasks that affects the ability of students with disability to demonstrate their knowledge (AERA et al., 2014). From a validity perspective, the most important theoretical construct in quality assessment, that is, that an assessment is measuring the learning it is intended to assess, and an appropriate interpretation can therefore be made about the learning that has occurred. “Noise” may mean that an assessment outcome and interpretations made from the outcome may be invalid.

The key point in assessment adjustments in accessibility. Although assessors may have demonstrated reluctance to change assessment practices, many alternative modes of determining what a student with disability knows and can do are available. One approach to identifying what learning is to be demonstrated, drawing on alignment with the curriculum that has been taught (or was intended to be taught), is to identify the “target” knowledge and skills that are to be assessed, and “access” skills, the skills required to complete the assessment (Dembitzer and Kettler, 2018; Kettler and Elliot, 2010). Target skills are the essential elements of an assessment. “Access” skills may impede the outcomes for target knowledge and skills that a student with disability can demonstrate, for example, reading print material may not be a suitable target for students with vision impairment, but a different form of

“reading” may be able to be substituted. Where a student’s disability is such that the intended target skills are not appropriate for their age/peer level, then target skills may also be addressed.³

Core assessment issues of validity, interpretation and reporting arise when target skills, and on occasion, access skills, are adjusted. As noted, Australian law indicates that adjustments are not required if the “integrity,” hence, validity, of an assessment may be compromised. What is reported should be what a student can do. It is frequently commented that even students with disability have the right to fail if they do not know what is being assessed, if the assessment itself is a fair task. For many assessment adjustments, an issue is whether there has been reduction of cognitive load, with consequent impact on the validity of the assessment (Andersen et al., 2018). Conversely, cognitive load may be increased for students with disabilities in comparison with their peers without disability, if a task requires excessive and inappropriate access skills.

When different forms of adjustments (and modifications) occur, grading and reporting are an issue that authorities, teachers, students and parents must address. One consideration is whether grading and progress should be peer-related, standards-related or ipsative, depending on the nature of a student’s disability and their education program (Quenemoen et al., 2003). Again, there is no easy answer to this. If the import of an assessment adjustment is to enable the student with disability to be assessed on the same basis as other students, while preserving the integrity of an assessment so that the outcome does not purport that a person can do something that they are not independently capable of doing, then the question is whether the reported outcome should indicate that the assessment has been modified. Again, this is contextual. A noted legal case in Ireland concerned a challenge against an amendment to certification that noted the nature of an adjustment (for discussion of the case and issue see Nisbet and Shaw, 2020, p. 82). Many drivers, like the authors of this chapter, wear glasses to compensate for a degree of vision impairment. Driving assessment is undertaken with the candidate wearing glasses. A resulting driving license has a condition that glasses should be worn when driving. This does not cause sensitivity for the driver but does alert others to conditions under which the driver can operate independently and safely.

In principle, schools and classrooms have a range of options available to assess the learning of students with disability. In principle also, such options could be made available for all students. A simple example is a critical “reading” of a novel for more mature students. The target skill would be understanding the author’s intentions, character development, the nature of a plot and so on. There may be a choice of novels. If some students with disability are not able to work at the level of their peers, they could be set a more simple novel. The act of reading as decoding is not necessarily a criterion for successful completion of the task. Students with a visual impairment may have an audiotape of the novel, some students may view a fair visual representation of the novel through a video or film. A degree of scaffolding to structure responses might be provided for all students to assist in the task. Students could then be offered a range of presentation formats from an essay, handwritten or with an option to use technology, including voice technology—(really more appropriate in the 21st century for all students), to an oral presentation with or without technology, or pre-recorded, to the class of students or in a singular setting with a teacher for students whose disability characteristics include anxiety. These are just some of the options that could be available for the task, with the focus on whether the student can demonstrate the understandings of the novel that are the essential target skills. These options have been recorded in research on classroom assessment with students with disability, and adjustments in education (Dickson and Cumming, 2018). They do require teachers who are confident in equating the demands of assessment tasks and understanding the needs of their students with disability.

However, in practice, most classroom assessment adjustments mirror the range of assessment options available in national assessment programs and/or standardized test settings. It is in this area that most research on adjustments/accommodations/adaptations for students with disability has been undertaken. In these settings, adjustments commonly include different formats such as font size or technology assistance, availability of scribes and readers in some circumstances, students placed in separate venues to minimize distraction to the student with disability and to other students, and, most frequently, extra time to complete an examination or test. There is limited research still on the effectiveness of these adjustments and optimal adjustments, such as the sufficiency of extent of extra time. A number of theoretical frameworks have been used to examine the impact of accommodations. For example, one approach is that any accommodation, even if provided to all students, should provide most benefit to students with disability, a differential boost (Sireci et al., 2005), alternatively considered as a maximum potential thesis [MPT] (Zuriff, 2000).

A concern noted with most empirical research on adjustments in these contexts is that they address students as group members, whereas most students with disability have idiosyncratic characteristics affecting their learning and assessment. A further issue with most of the available empirical research is that while studies which address adjustments need to address access skills, the focus is on student achievement outcomes, rather than considering the appropriateness, that is, fairness, of the process (Nisbet and Shaw, 2020), and accessibility of assessment tasks. Little empirical evidence still exists on the effectiveness of different adjustments: how much extra time is desirable to enable optimal demonstration of a student’s knowledge and skills without leading to boredom or lack of concentration; under what circumstances should tasks be read aloud or does this increase the cognitive load for the student with disability who has to remember as well as respond, as noted by students without disability (Kim, 2012); how much time is needed for a student who is reading braille (Ragosta and Wendler, 1992). By contrast, both educators and students express concern about the fairness and potential advantage offered to students with disability when alternative forms of assessment are available (O’Neill, 2017; Rasooli et al., 2021; Tomlinson and Moon, 2013).

³In the US, such adjustments are recognized as modifications to the assessment goal (Kettler et al., 2018).

Legal perspective

The appropriateness of adjustments, and student outcomes, are the focus of most considerations of assessments for students with disability from the *perspective of law*. In Australian law,⁴ most challenges are based on the discrimination laws, and the DSE, including the concept of “reasonable adjustments” versus “hardship.” As [Dickson and Cumming \(2018, p. 321\)](#) summarized, such challenges have addressed denial of adjustments by the education provider, and hence indirect discrimination by requiring students to comply with unreasonable conditions which disadvantage them in completing assessments. Assessment adjustments considered in the context of legal challenges include

- Extra time to finish an exam or assignment
- Completing a course over a longer than usual time
- Supervised rest, food and medication breaks in examinations
- Adjustment to the format of an exam paper—font, paper color and size, paper “masks”
- Separate venues to minimize distraction or to accommodate assistance animals
- Alternatives to writing—viva voce, examination, scribe, assistive technology
- Alternatives to reading—brailled and/or taped materials, assistive technology
- Alternatives to hearing—written stimulus materials, translators, assistive technology
- Alternatives to speaking—written rather than spoken responses allowed
- Adjusted scheduling of assessment.

Three challenges noted by Dickson and Cumming are of a different nature. Two relate more specifically to how assessments are used to obtain a grade and report on the grade.

- Adjusted level of achievement thresholds where performance on a particular item has been compromised by disability (“special consideration”)
- Adjusted weighting of assessment for students who have missed an assessment item because of disability

One challenge relates to direct discrimination, less favorable treatment alleged by a student who wished to undertake an assessment but was excluded by the authority on the basis of their disability. This enforces the sense that students with disability do not wish to be seen as different from their peers. A further note is that in some of the cases, students were doing well or had potential to do well in their studies, that is, better than average, if assessment adjustments they identified as appropriate were provided. In these cases, concern was expressed in the court judgments that adjustments should not advantage students with a disability. Students are likely to be successful in challenges under the DSE if they are able to establish that an adjustment would have enabled them to achieve a better result, where an inappropriate or no adjustment has been provided. They are generally not likely to be successful if the education provider can show that consideration had been made of the nature of the student disability, adjustments were provided, and these were deemed reasonable ([Dickson and Cumming, 2018](#)).

From a legal perspective in Australia, therefore, assessment adjustments should be provided to address the consequences of a disability of a student, unless this compromises the integrity of the assessment. Integrity or validity are not issues which are argued frequently in Australian court cases, although these have occurred in cases in higher education ([Dickson, 2012](#)), but are more frequently raised as validity issues in cases elsewhere, especially in the US ([Pullin and Cumming, 2022](#)). However, clear evidence of a failure to make reasonable adjustment and related indirect or direct discrimination may lead to a successful challenge by an individual student with disability. From the student’s perspective, this should ensure a fairer process and lead to a better outcome. From an assessment perspective, this would increase the validity of the assessment and most importantly interpretations made from the assessment. This brings us to the core issue of national (Australia) and international test programs and the assessment of students with disability.

Accountability at national and international level and inclusion of students with disability

Many countries have national assessment programs intended to monitor student progress. Different reasons are proffered for these programs from monitoring the educational quality of a state or district, the quality of a school, the quality of a teacher, and the learning and progress of an individual student ([Cumming et al., 2019](#)). Test formats vary from traditional paper-and-pencil to more recent use of technology and ICT ([Eurydice, 2009](#)). Where digital assessments are being used, countries are also making use of adaptive testing, where the achievement level of students is gauged from initial questions, and the student is then scaffolded as appropriate into more difficult or more easy questions ([ACARA, 2016c; Eurydice, 2009](#)). Adaptive tests are seen as more suitable for assessment with students with disability as they enable greater differentiation without increasing the length of a test, reduce

⁴As noted, Australia does not have a history as a litigious nation in education, with most challenges settled through mediation or out of court, including cases where students were found to have been taught the wrong curriculum for a certification examination, similar to cases regarding assessment and opportunity to learn in the US. The cases noted in [Dickson and Cumming \(2018\)](#) represent those that have made it to the courts. For discussion on US assessment law cases, see, for example.

anxiety, increase student engagement, and reduce student discouragement due to repeated failure, while at the same time enabling high achieving students to have more challenging tasks (ACARA, 2016c).

The Australian National Assessment Program (NAP) monitors the achievement of all students in literacy and numeracy in specific year levels in Australian schools (National Assessment Program—Literacy and Numeracy [NAPLAN]) and conducts sample assessments in other areas. In addition to national assessments, the NAP incorporates participation in international sample tests such as PISA, TIMSS and PIRLS to enable international comparisons.

The Australian NAPLAN and other national NAP tests make provision for adjustments for students with disability. With the recent introduction of online testing, these include

- Assistive technology
- Alternative format tests
- Scribes and support persons
- Reading to students
- Extra time and rest breaks
- Separate location (ACARA, 2016a).

Online tests also enable “alternative questions” that can be responded to by students with disability engaging with, to use prior terminology, the same target skills as the original question formats. Alternative questions may be through audio, visual and colored presentations (ACARA, 2016a). Some adjustments will assist in reducing the cognitive demands on a student with disability. Clear guidelines are provided to ensure that no advantage is provided to a student with disability and that the resources used are those that the student would normally access in the classroom. By contrast, not all resources a student might use in the classroom will be available for NAPLAN (ACARA, 2016b; Davies et al., 2016). The expectation is that all students will complete NAPLAN and NAP assessments, however, “some students with significant intellectual disability and/or students with significant coexisting conditions, which severely limit their capacity to participate in the tests, may be exempted from sitting the tests.” (ACARA, 2016b). In 2019, between 1.6% and 1.8% of students were exempted from assessments across the year levels of testing (ACARA, 2019). According to national data, in 2020, some 20% of Australian students are identified as having a disability that requires some form of school support, with 1.6% having an “extensive” disability, and 3.4% having a “substantial disability” (ACARA, n.d.). While these figures may be consistent with those who were exempted from NAPLAN testing, the learning progress of a percentage of students is not being captured. Students who are excluded are directly discriminated against in the NAPLAN assessments on the basis of their disability. In terms of adjustments, NAPLAN is more inclusive than previously (Cumming and Dickson, 2013; Cumming et al., 2013). However, a key issue remains. A large number of students with disability may be receiving adjustments in completing the assessments. Information on the performance of these students and the nature and quantity of adjustments are not reported to the public. The implicit assumption is that the testing format and adjustments provided are valid and appropriate to allow students with disability to demonstrate their learning in these key areas at an optimal level. Conversely, a further implicit assumption is that interpretation of the achievement of these students in comparison with other students is also valid.⁵ These are major assumptions regarding the appropriateness of these assessments to judge the learning of students with disability, and of their cohort and school. For students who do participate in the tests, where the adjustments that are made are not sufficient to address their needs due to the consequences of their disability, indirect discrimination has occurred.

Like a large number of countries internationally, the NAP includes participation in international tests such as TIMSS and PIRLS (<https://timssandpirls.bc.edu>) and PISA (<https://www.oecd.org/pisa/>). The purposes of these tests are mixed. They provide global comparisons of achievement for participating countries, although they have also been defined as showing “how education systems provide educational opportunities to their students, as well as factors that influence how students use these opportunities” (International Association for the Evaluation of Educational Achievement [IEA], 2021). This could be interpreted as consideration of how countries address education of the diversity of students, including students with disability.

Tests are conducted by sample testing. However, TIMSS and PIRLS still exclude students in schools that are only for “special needs students” including students with “functional disabilities” who cannot complete the TIMSS tests and students with “intellectual disabilities” including students “who are emotionally or mentally unable to follow even the general instructions of the test.” Students with learning disabilities are to be “accommodated,” rather than excluded (LaRoche et al., 2020, Chapter 3.6). The Australian TIMSS report indicates that “non-mainstream schools (such as schools for students with special needs)” were excluded with further within-school exclusions of students with intellectual and functional disabilities (Thomson et al., 2020, p. 153). In Australia, for the 2018 PISA round, students were excluded on the basis of “moderate to severe permanent physical disability,” or cognitive delay due to “cognitive, behavioral or emotional disability” (Thomson et al., 2019, p. 247). OECD statistics for the same round indicate 623 Australian students were excluded due to special education needs (OECD, 2019, Table I. A2.4). Standard adjustments for standardized tests are now available for school administration (cf Cumming and Dickson, 2013; Cumming et al., 2013) and PISA is noted as aiming “to be as inclusive as possible ... [with] strict guidelines enforced with regard to the percentage of schools and of students that could be excluded” (Thomson et al., 2019, p. 6). For PISA, the intention was that special education settings would be included in sampling, however, in Australia, these schools are only attended by students with disability who would

⁵It should be noted, however, that interpretation of NAPLAN scores for individual students with or without disability, and their learning progress, is problematic due to measurement error (McGaw et al., 2020; Wu, n.d.). For students at the extremes of the distribution of scores for their Year level, as might occur for many (but not all) students with disability, the problem increases (McGaw et al., 2020).

meet the exclusion criteria. Alternative assessment booklets are available for students with disability, but were not used in Australia. Many countries have been reported as providing participating students with disability with the standard range of test adjustments to ensure that they are not practicing indirect discrimination according to their legislation (LeRoy et al., 2019).

National and international test regimes will undertake preparatory, and ex post facto, analyses to establish the construct validity, that is, the match of the test focus, to desired curriculum learning. In administering such tests, given the focus on comparability for interpretation, the emphasis is on reliability, rather than validity, with limited involvement of students with disability a consequence (LeRoy et al., 2019). Consistency in administration and scoring become important. Standardization of procedures ensures such comparability. There have been developments to make these tests more inclusive, enabling participation of students with disability. However, students may not only be excluded but also little information is provided about the nature and extent of any adjustments provided for students with disability—"their presence is invisible" (LeRoy et al., 2019, p. 3). If one purpose of such assessments is to inform countries on the quality of their education provision for all students, including students with disability who must be included in the sampling, there is an "informational vacuum" with respect to the education of students with disability (p. 3). The overall validity of these international accountability assessments in terms of student outcomes and interpretation of overall performance may be questioned.

Conclusion

Inclusive education of students with disability is an idealized international and national goal. Inclusive assessment practices with students with disability are an essential component of education overall. Models of disability increasingly recognize the situational nature of disability. Disability is not a medical diagnosis but arises from the social and practical consequences of the characteristics of a disability in interaction with society. From a social perspective, inclusive education is sited within human rights, social justice and equity. Through such perspectives concern is with fairness, a concept which has defied precise definition. At the ideal, inclusive education would result from principles of Universal Design, so that all are included, all are different, and education goals, engagement and outcomes are clear for all students. Inclusive education as a social endeavor has been translated into national and international policies. Providers and schools endeavor to implement inclusive education through the full inclusion of students with disability, and hence to ensure that students with disability are able to access and engage in educational assessments. At a realistic level, and within societal context in the provision of education, Universal Design is seen to have limitations. Differentiation in provision and assessment become the goal, keeping expectations for the achievements of all students, including students with disability, high. In educational practice in schools, administrators, teachers and students work through the daily challenge of addressing the needs of students with disability to ensure that the education provided is as fulsome as possible, and that educational assessments are accessible and allow students to demonstrate their achievement at as high a level as possible. In most countries, as exemplified by Australia, these ambitions are supported by legislation that prevents discrimination, either direct or indirect, against students with disability.

Inclusive education has been noted to be aspirational, ambitious, and hopefully moving forward. Some clarity of processes and procedures is emerging through policies, practices, and to a lesser extent, the law. Differentiation addresses the consequences of the characteristics of students with disability to enable them to be on a level playing field with their peers without disability. It cannot remove the disability, it is not a deficit model, it is a practical approach. However, enacting differentiation in assessment is complex and demanding. It requires considerable experience and confidence of educators, that is yet to be fully realized. It requires further empirical research on what is the best approach to assessment for students with disability to enable optimal but valid achievement. The challenges that remain are the beliefs and experiences that shape teacher, student and community experiences: perceptions of fairness, equity, advantage and disadvantage. From a social perspective these are broad issues, from the educational assessment perspective, the options are more restricted, from a legal perspective, within educational settings, interpretation of legislation and provision are further restricted. Unfortunately, from national and international accountability assessment perspectives, these are unknowns.

“Accountability” is one of many polysemous concepts which have become increasingly employed in academia and policymaking in education. Its core meaning refers to someone being held to account for their actions or outcomes by a third party and implies that the latter possesses a form of legitimate authority over the former. School principals have the authority to hold teachers accountable for their actions and outcomes; professional bodies are authorised to hold teachers accountable for their actions; and inspection agencies are charged with the task of holding schools accountable for their pupils’ performance and the quality of schooling. The core purpose of accountability based on outcomes, as opposed to process, is the assumption that improvements can be elicited by measuring. Högberg and Lindgren (2021) describe the three steps by which this is realized: the production of standardized performance data which serves as a proxy measure of the quality of education; its evaluation by external parties; and incentives and or sanctions resulting from the evaluation.

An extensive literature has described the increased role of such systems of outcomes-based accountability and portrayed them as central to the “New public management” (NPM) reforms associated with the rise of neoliberalism which promoted the practices of the private sector into the education sector (Hogan et al., 2021). This encouraged a climate of “performativity” which resulted in individual practitioners organizing themselves to constantly respond to targets, indicators, and evaluators. This shift has been manifested in policies designed to increase the autonomy of schools and from states governing schools directly to forms of more indirect governance based on “steering at a distance”. Modes of outcomes-based accountability exercised through national agencies like the schools inspectorate OFSTED in England, have become the primary means by which states operationalize accountability, especially within contexts where governance reforms have sought to decrease direct state control, increase school autonomy and parental choice (Asadolahi et al., 2022).

The rise of such systems of accountability has developed in tandem with the shift from envisioning schools as providing pupils with forms of knowledge based on different school subjects to expecting that they equip them with useful skills or competencies (currently described as “21st Century Skills”). Originating in the US economic policy reports “A Nation at Risk” (National Commission on Excellence in Education, 1983, online) and “What Work Requires of Schools” (Secretary’s Commission, 1991), the discourse around the necessity of skills like collaboration and critical thinking has increasingly dominated global education initiatives, and is now reflected in local education policies across a range of countries. Anderson-Levitt and Gardinier (2021) note that UNESCO’s original interest in such skills was to enable individuals to be better citizens in increasingly multicultural democratic societies (Delors, 1996); and the OECD extended that rationale by stressing the need to prepare citizens who can address environmental emergencies facing the globe (OECD, 2019). However, those humanistic aims have been largely replaced by an economic rationale which claims that, in line with human capital theory, in the new “global knowledge economy”, citizens must be prepared in schools to exercise interdisciplinary skills, or “competencies” – that are increasingly demanded of workers and professionals for the sake of their own individual success as well as the prosperity of national economies (Robeyns, 2006).

Our focus is on Outcomes-Based accountability that derives from cross national studies of pupil performance, or international large-scale assessments (ILSAs), which have emerged in the 21st Century as a powerful influence on education policies in many nations.

The chapter begins with a brief analysis of the history of ILSAs and their key features, focusing on their sources of legitimacy and the conflicts inherent in their modus operandi. It then identifies the logic and central assumptions which underlie ILSAs as a form of accountability. Finally, the chapter provides an overview of the major critiques of this form of accountability, focusing on PISA.

International large scale student assessments

The first ILSA was undertaken by UNESCO’s Institute for Education in 1962. The Pilot Twelve Country study involved 12 000 13-year-olds and its results were published in 1962 (Forshay et al., 1962). From this the International Association for the Evaluation of Educational Achievement (IEA) emerged which then conducted a series of international evaluations. The IEA now conducts the 4-yearly Trends in Mathematics and Science Study (TIMSS) and the 5-yearly Progress in Reading Literacy Study (PIRLS). The IEA

studies are not wholly standardized as they test pupils on the curriculum they have studied, which clearly varies across nations; and advice arising from them is tailored to individual countries in separate reports.

The latest generation of cross-national tests has been developed by the OECD as part of the Program for International Student Assessment (PISA). PISA assessments have been conducted every 3 years since 2000, in reading, mathematics, and science. Each cycle also includes an “innovative domain” – these have included problem solving, global competences and critical thinking. PISA is a standardized test designed to measure the skills required by 15-year-old pupils entering the workforce. In 2000, 43 countries participated and by 2018 that had increased to 79 participants, including what the OECD calls “jurisdictions” such as Shanghai. The triennial release of the PISA League Table rankings of the performance of pupils across nations attracts a great deal of media scrutiny and has generated reactions varying from national pride, (for example, in Singapore), shock and shame (Germany, Denmark and England) to ambivalence (USA, France) (Waldow et al., 2014; Engel and Frizzell, 2015)

The OECD has worked in conjunction with the media (Grey and Morris, 2018) and with a powerful global network of actors to make PISA the most prominent and influential ILSA and contributed to the emergence of a global system of educational accountability and governance. That network comprises other cross-national organisations, such as the World Bank and UNESCO, and companies such as McKinsey and Pearson which have positioned “competitive comparisons” based on ILSAs as the basis for measuring, evaluating and reforming national educational systems. ILSAs, by virtue of comparing pupils across nations and cultures, are far easier to operationalize if they are assessing and comparing based on a universal and standardized measure (defined as competencies) rather than one which, like those of the IEA, reflects the curricula in different nations. As will be demonstrated, while their legitimacy and mode of operation differ from national systems of outcomes accountability, their influence on many of those systems has been powerful; although it has been far greater in some nations than others (Pultar, 2021).

AS PISA has grown, so the OECD has also extended its testing empire to include more populations and concepts. Fig. 1 shows the range of tests it has developed.

These now include tests for pre-school children (IELS); university students (AHELO); and adults (PIAAC). PISA has primarily involved more affluent nations, having originally been offered only to OECD member states. Few low- and middle-income nations have joined and some which did take part, performed poorly and subsequently withdrew. India, for example, withdrew, claiming that the test was not sufficiently suited to the Indian context after it was outperformed by all other nations except for Kazakhstan (Addey, 2016). In an attempt to attract low and middle income nations, the OECD ran a pilot project, termed PISA for Development

Programme/Start date	Who is assessed?	Subject Areas	Sources of context information	Frequency	Coverage
OECD PISA (2000) Programme of International Student Assessment	15 year olds in FT education.	- Reading - Mathematics - Science - Collaborative problem-solving (2015) - Global Competency(2018)	- Students - Parents (optional) - Teachers (optional) - School principals	Every three years since 2000	OECD countries: 34 Non-OECD participants: 38 (PISA 2015)
OECD PIAAC (2013) Programme for the International assessment of Adult Competencies.	16-65 year olds	- Literacy - Numeracy - Reading components - Problem-solving in technology-rich environments	- The individuals who are assessed	Every 3 years	OECD countries:24 Non-OECD participants: 2 (PIAAC 2011)
OECD TALIS (2008) Teaching and Learning International Survey	Teachers of lower secondary education	(Focuses on the learning environment and working conditions of teachers)	- Teachers - School principals	Five years between first two cycles Since 2008	OECD countries: 16 Non-OECD participants: 7 (TALIS 2008)
OECD AHELO (2012) Assessment of Higher education learning Outcomes	University students at the end of B.A. programme	- Generic skills common to all university students (such as critical thinking) - Skills specific to economics and engineering	- Students - Faculties - Institutions	A feasibility study was carried out in 2012	Institutions from 17 countries participated in the feasibility study in 2012
PISA for Schools (2013)	Cohort of 15 year olds in a school – at least 42 students and 80% participation	Same assessment framework as PISA	As for PISA	Rolling programme, ‘on demand’, maximum of once per school year	Currently available in 11 countries and 10 languages
OECD PISA-D (2018) PISA for Development	15 year olds in school and some ‘Out of school’ 14-16 year olds.	- Mathematics - Reading - Science (in school only)	- Students - Teachers - School principals	Results of a pilot round in 9 countries to be released in Dec 2018, merging with PISA in 2021	Low- and middle- income countries (9 pilot countries)
OECD IELS (2018) The International Early Learning and Child Well-being Study	4/5 year olds.	- Emergent literacy - Emergent numeracy - Empathy and trust - Self-regulation	- Parents - Staff	2017 field trial/Pilot 2018 Main Study	Pilot Study in USA, England & Estonia

Fig. 1 OECD international comparative education tests (Taken from Grey, 2020).

(PISA-D) with modified questions and metrics tailored toward the educational realities in the global south; which was completed and declared a success by the OECD in 2018, notwithstanding some critical analyses (Auld et al., 2020; Li and Auld, 2020).

In contrast to national systems of inspection and evaluation designed to hold individual teachers or schools to account and/or to provide comparative data to promote school competition and school choice, the OECD, as an organization concerned with economic coordination and the promotion of market economies, has no official mandate in the field of education. The focus of PISA is on educational systems, and it has no power to provide rewards or impose sanctions. Thus, in contrast to national systems of outcome-based accountability, the legitimacy of the external agent, the entity being held to account and the potential incentives/sanctions of cross-national systems are opaque and loosely coupled. As Meyer comments:

the din about changes in rankings is masking the even more profound problem that in the wake of 15 years of PISA assessments, democratically elected national authorities are increasingly ceding control over their schools to an unelected, unaccountable body of OECD experts.

Meyer (2013).

These “experts” are, significantly, not “experts” in education, nor even in policy, but are largely economists and statisticians – the Director of Education himself has a background in theoretical physics. Notwithstanding, PISA has emerged as the largest and most influential cross-national test that has been instrumental in initiating education reforms across nations and specifically in promoting systems of outcomes-based accountability within many nations (Verger et al., 2021).

The OECD Director of Education, Andreas Schleicher, who pioneered PISA after a brief career at the IEA, describes PISA as “the world’s premier yardstick of educational quality” and explains its value thus:

Comparative international evaluations can extend and enrich the national picture by providing a larger context within which to interpret national performance. They have gained prominence – over recent years – since the benchmarks for public policy in education are no longer solely national goals or standards, but, increasingly, the performance of the most successful education systems internationally. International evaluations can provide countries with information that allows them to identify areas of relative strengths and weaknesses, and monitor the pace of progress of their educational system. They can also stimulate countries to raise aspirations by showing what is possible in education, in terms of the quality, equity, and efficiency of educational services provided in other countries or regions, and they can foster better understanding of how different education systems address similar policy challenges

Schleicher (2010).

ILSAs are thus portrayed as an accountability tool that can assess policies and policymakers against “benchmarks” which compare the performance of nations with the most successful and provide them the opportunity to learn from “world class” policies and “best practices”. Unlike more established and local forms of accountability, which in themselves are contested and ambiguous (Christensen and Lægriid, 2015) this new form of accountability to globalized norms based on numbers and datasets lacks a direct hierarchy in which an “agent” (a manager, or an organization) offers feedback to an actor (a teacher, for example), who is then expected to demonstrate “improvement”. Personalized or tailored targets which previously would have served to focus performance on a set of outcomes are now replaced by fuzzy exhortations to match the world’s best, and to strive for continued improvement against a set of shifting criteria defined by scores and rankings on PISA.

Thus, schools are no longer only accountable to their students or to local education policymakers and evaluations. Since around 2012 the OECD has made explicit the underlying rationale for the instrument: that improving PISA scores contributes directly to economic growth, and that the future prosperity of a nation is also at stake. The logic is that PISA will not only help nations to improve the intrinsic quality of their schooling but that those improvements will increase economic growth and their capacity to compete in the global knowledge economy. As the OECD explains:

For the USA, an increase in GDP of 25 PISA score points will increase GDP by \$41 trillion (OECD, 2012, p. 2)

And:

If Ghana could educate all of its students to at least the basic level of reading and mathematics skills [on PISA], it would see a gain over the lifetime of children born today that, in present value terms, is 38 times its current GDP (Schleicher, 2018, p. 139).

The OECD, in contrast to the IEA, has become heavily involved in policy advocacy and thus acts as not only the collector of performance data but also interprets it to promote the “best practices” inferred from features of high performing nations. This dual role allows the OECD to design, collate and disseminate data which it then also translates into carefully framed policy messages, aimed at entire school systems but largely unamenable to school-level intervention. A form of “Soundbite governance”, resting on slogans such as “the quality of an education system is only as good as its teachers”; “Money makes a difference ... but only up to a point”, and the all-important mantra, “Your school system today is your economy tomorrow” (OECD presentations, various

sources), is backed up with literally hundreds of documents, videos and webpages, which are aimed at an ill-defined audience, but are generally consumed by media actors and transferred to media audiences in edited and diluted format.

The scientific expertise necessary for test design, data collection and reporting has thus become entangled with the construction and narration of policy stories (Stone, 1989) which are passed into the public arena via the media. This narrative revolves around identifying what is wrong (usually framed as a crisis), the ideal promised future and the proposed solution. The solutions are derived from the myriad of possible policy stories that can be constructed from the data and the problems are framed in a way which leads inevitably toward the solution identified (Auld and Morris, 2021).

Two fundamental problems arise from the OECD performing both those roles: firstly, a tendency for the organization to collect, interpret and highlight data in ways which confirm the policies and “best practices” which they advocate should be adopted by nations; and secondly, an unwillingness to acknowledge any weaknesses in the test design, data analysis or interpretation given that they have been directly used to promote and initiate policy actions. The OECD has addressed these conflicts of interest by a strategy of either not engaging with critics, or by resorting to *ad hominem* responses. “Who is opposing this?” Schleicher asked in 2015. He answered his own question; “people from pedagogy, not really anyone else” (Schleicher, 2015). Criticisms are skilfully deflected by a man who is highly experienced in dealing with both the media and academia, as the example below demonstrates. In his drive to ensure that the world’s school systems are accountable to data, Schleicher himself remains essentially unaccountable:

I think the methodological robustness is beyond question. I don’t worry about it, when I get those questions, I provide the answers and I think very soon this dies down ... the bigger question is, are our metrics complete ... ?

Schleicher (2015).

PISA’s legitimacy as a powerful source of influence on educational policy making derives from a multitude of interconnected factors. As a global metric presented as a numerical league table of comparative performance it bears the hallmarks of an objective test undertaken by scientific experts unsullied by ideological considerations. It provides a ranking of performance which is shaped by and tailored for media stories (Grey and Morris, 2018) of national pride or shame; crisis, failure and blame. It provides national politicians with a wide range of correlations from which to select and develop an “evidence based” policy story, which supports their own ideological preferences and related policy stories (Auld and Morris, 2021), in which the reasons for poor performance and the path to salvation are identified. This path requires emulating the “best practices” and policies of high performing nations or “world class” systems.

In domestic political arenas the global nature and source of the data can also help overcome political resistance and encourage coalition building. PISA is also constantly validated and legitimized by the Global Education network and industry (Mohammed and Morris, 2019), which operates a business model reliant on interpreting PISA data to identify “what works” and sell solutions. The OECD also provides a convincing strategic narrative which includes portraying those who do not follow its advice as reactionaries or ideologues who are not committed to improving the quality of education; claiming that PISA offers a path to economic growth; and portraying a vision of an idealized future for those who follow its advice.

The impact of PISA on national education policies emerges from the ways in which evaluation by both the OECD and external parties of a nation’s performance on PISA is undertaken in a public arena by a combination of stakeholders, almost all of whom lack a democratic mandate. The media, domestic politicians, commercial consultancies, global agencies like the World Bank, as well as the OECD itself, all act on and shape the perceptions of PISA in local political spaces, and all benefit, directly or indirectly, from its ongoing and dynamic presence. PISA has thus contributed to a continuing shift to what Gleckman (2018) describes as “multi-stakeholder global governance”; the key feature of which is that control, in this case of the system of accountability, shifts from nation states to those who provide or benefit from the activity. Agency is often obscured, and the rhetoric of competition and the imperative of economic growth become “common sense” objectives, against a backdrop of the need to skill future workers to thrive in a globalized arena. This narrative presents some difficulties for the OECD; for example, with the passage of time it has become clear that there is a gap between the promissory vision and reality. PISA is marketed on the basis that its comparisons provide the basis for improving pupils’ learning in participating nations (and that this will result in economic growth). However, despite many nations apparently following the best practices promoted by the OECD, that improvement has not generally materialized. As the OECD explained in 2019: “it is disappointing that most OECD countries saw virtually no improvement in their students’ performance since PISA was first conducted in 2000”. (OECD, 2019, p. 3).

The same outcome is evident outside the OECD. The nations of the Arabian Gulf have relied heavily on the policy advice derived from ILSAs and have, in conjunction with their network of consultants and private outside companies identified improving their scores on ILSA’s as the goal of their education reforms (Mohamed and Morris, 2019). However, a review of the reforms implemented on the basis of the recommendations arising from the involvement of these agencies concluded:

Over the past decade and a half, key countries of the Gulf... have invested considerable resources in education. Driven by a desire to better prepare their economies and societies for an increasingly globalised and competitive world.... And yet despite the availability of ample financial resources and expert policy and management advice, most independent reviewers have concluded that the actual results have fallen short of initial expectations.

Alfadala (2015, p. 4).

The reason given for this was:

Most, if not all, of these outcomes were found to stem from a single, underlying response to the reforms being introduced: resistance to the change. Alfadala (2015, p. 7).

While allocating the blame for failure to local teachers and decision makers is a standard strategy employed in the “gray literature”, most particularly by the media (Grey, 2020), it conveniently avoids any consideration of the policy making process and its reliance on ILSAs.

Much of the academic literature on PISA has involved secondary analyses of the data designed to identify trends, patterns and correlations (Hopfenbeck et al., 2018). Here we instead focus on how PISA is used to influence policy by undertaking a critical interrogation of the logic and assumptions on which it is constructed. We argue that a comprehensive understanding of why ILSAs have failed to deliver requires the recognition that the PISA enterprise is built on weak foundations. However, by locating blame for failure within local conditions and actors, agency is removed from the OECD or its recommendations, which, ironically, are made without reference to those same local conditions. The quest for world-classness is culture-blind; not so the post-mortems when policy interventions are considered to have failed to deliver the hoped-for results. “They didn’t change the culture, they changed what they did in education”, said Andreas Schleicher in 2015 of Poland’s improved scores on PISA (Schleicher, 2015, online), illustrating that while failures can be blamed on local conditions, successes are seen to validate the mission and support the strategies promoted by PISA.

Logic and assumptions

The logic underpinning the policy advocacy which is central to PISA’s influence derives from asserting a strong connection between economic performance, competition/survival in the global/knowledge economy and the quality of schooling/education, as measured by cross national tests. The basic logic can be stated thus (Morris, 2015):

- a. Country A is growing rapidly and is competing successfully in the global knowledge economy, which is largely the result of the educational system producing workers with the required skills as evidenced by international tests.
- b. Country B has the opposite features to Country A.
- c. If Country B adopts the critical features of the educational system of Country A, it will improve pupil performance, the state of the economy and its capacity to compete in the global knowledge economy.

This logic, while presented in a far more subtle and convincing manner which constantly recognizes and then ignores its reductive nature and limitations (Auld and Morris, 2014), provides policy-makers with a clear logic for reform. It is premised on the following assumptions:

- (1) economic success in a nation state is primarily a function of schooling within that nation and the development of human capital. Tests of pupil achievement, such as PISA, provide a reliable measure of a nation’s stock of human capital and therefore of future economic growth and competitiveness.
- (2) The tests are valid and reliable.
- (3) The causes of pupil performance lie primarily within the educational system.
- (4) The cause(s) of high performance can be isolated and policies based on those causes can be transplanted into a different context.
- (5) The evidence is faithfully and consistently considered and the policies advocated are coherent insofar as they are validly derived from that evidence.
- (6) The policy actions taken to improve test scores also serve to improve the quality of education.

These assumptions provide the foundations upon which this form of accountability is constructed and how that is translated into policy advocacy. Below we highlight the key issues associated with each of them.

The focus of the *first assumption*, that economic success is primarily the function of a nation’s quality of schooling is oft repeated and central to the discourse of global governance. It is not supported by the evidence other than that provided by the work of Erick Hanushek, on whom the OECD rely (with Kimko [Hanushek and Kimko, 2000]; then later with Ludger Woessman [Hanushek and Woessmann, 2010, 2015]). A study by Kamens (2015) who traced the historical relationship between test scores and economic growth from 1963, concluded that “the linkage between national test scores and economic growth is weak and inconsistent” (Kamens, 2015, p. 436) and that “countries with higher test scores ... are not more likely to experience later higher economic growth. (Kamens, 2015, p. 441). Komatsu and Rapple (2017) scrutinized the claims of Hanushek and Woessman, addressing in particular the ease with which their methodology was misunderstood and therefore remained largely unchallenged. Their conclusion – that the work upon which PISA is based is both inaccurate and misleading – has important implications for policymaking and governance. In a later article (Komatsu and Rapple, 2017a), the authors go further, suggesting that explicit linkage of economic objectives with student performance actually serves to reduce student performance, when promised economic gains fail to materialize, thus “undermin[ing] the core premise of the OECD’s whole approach to PISA itself” (Komatsu and Rapple, 2017a, p. 269).

Feniger and Atia (2018) also examined the relationship between PISA scores and economic growth and concluded that success in the former increased after the latter. This is not surprising as Hanushek and Woessman's analysis does not build in a time lag between educational outcomes and economic performance; and it ignores the influence of other factors (such as economic policies, capital investment and natural resources). Further, as Lauder (2015) argues, it does not recognize the global nature of modern labor markets. The relative influence of a range of factors is underlined by the evidence on labor productivity. If increasing PISA scores resulted in faster economic growth, this would be manifested in higher levels of labor productivity. Many nations with high levels of productivity, such as the USA, Italy and France, do not perform highly on PISA; and many high performers on PISA, such as Hong Kong and Singapore, have low levels of labor productivity (OECD, 2021). A similar pattern is seen in measures of innovation and inventiveness (Global Innovation Index, 2021).

The *second assumption* relates to the validity of the tests and the key question of whether what they measure is important.

It is not clear that the cognitive competencies measured by PISA are those that employers seek in their employees; PISA measures skills the OECD believes to be essential in the workforce and assumes that it is primarily success in STEM subjects that will generate economic growth. When surveyed, employers routinely identify teamwork, collaboration and oral communication skills as among the most valuable yet hard-to-find qualities in workers (e.g. Casner-Lotto and Barrington, 2006; Jerald, 2009). Deming (2015) also argues that social skills are a more powerful predictor of workers' productivity than cognitive skills, suggesting that advances in technology have primarily reduced the number of jobs that require cognitive skills rather than those which require social skills. Consequently, it is social skills that are increasingly valued and rewarded in the labor market.

PISA compares pupil performance in science, mathematics and reading, so inevitably, the tests focus on cognitive skills which are amenable to measurement. Competencies which are less easily quantified, such as critical thinking, cooperation and creativity are now assessed through proxies constructed to make them amenable to measurement; while competencies associated with other domains such as Art, Music, PE, Morality and Ethics are excluded. In essence, ILSAs measure that which is most amenable to measurement; and Biesta (2009) argues we have ended up valuing what we measure rather than measuring what we value. The potential reductive effect on the school curriculum is clear, and while education systems continue to be governed at a distance by the metrics of PISA, this narrowing remains one of the most significant dangers.

Acknowledging weaknesses around PISA, in 2018, Schleicher stated:

The current PISA doesn't include many elements that are important. We need to do better on social skills, on creative skills, so the new framework – the 2030 framework is really about developing new ideas for what PISA should assess. Education 2030 is about what should PISA assess, and what are the skills that are really important for success.

Cited in Li and Auld (2020).

We return to discuss OECD's vision of the future in the final section.

The *third assumption* relates to the longstanding debate as to whether student outcomes are primarily a result of the impact of schooling or of factors outside school (e.g. culture, parental expectations, private tutoring). If the levels of pupil achievement are significantly influenced by factors outside the school then the inferences that can be derived for educational policies are severely limited. While those advocating educational policies often acknowledge the influence of non-school factors, they tend to subsequently ignore their significance as they promote their own preferred education policy solutions.

The performance of populations of pupils from one culture schooled in another provides a basis for considering these claims. In all cross-national studies of academic achievement, Chinese pupils (from Hong Kong, Singapore, Taiwan and China) have been ranked among the top performers and these societies have been portrayed in England as education utopias. Studies by Feniger and Lefstein (2014) and Jerim (2015) examined the performance of Chinese students who have been born and schooled in Australia and New Zealand, respectively. They found that Chinese immigrant students performed at a significantly higher level than pupils who were native to those countries. This would suggest that influences outside the school have a powerful impact on pupil performance.

The *fourth assumption* is that the cause(s) of high performance can be isolated, and policies based on those causes can be transplanted into a different context. Unless a causal relationship can be established between the factor identified as promoting a high level of pupil performance, and improvement in that performance, any claim to have identified "what works" lacks a strong foundation. Yet attempts to promote policy interventions are often based on loose correlations, or confirmatory and selective observations. The claimed sources of high performance are often contradictory or pre-selected and confirmed or cited as a feature of a high performing system; but, importantly, there is no corresponding consideration as to whether poorly performing systems lack this factor (Auld and Morris, 2014). Thus, high performance on PISA has variously been associated with both traditional and progressive teaching methods; centralized and decentralized systems of control and with teachers and leaders. Claims regarding the features of selected high performing systems are used to deliver prescriptions for improving matters elsewhere. Further, many of the assertions, for example, that good teachers lead to high levels of pupil performance, are self-evident analytical claims (i.e. they are necessarily connected – good teaching is defined by its impact on pupil outcomes) and not empirical findings. Similarly, claims that good educational systems are characterized by "good/strong leadership" are axiomatic and banal. The network that uses PISA data to identify and advocate reforms has developed a sophisticated range of strategies to mask the often-weak basis of such claims about "what works" (Auld and Morris, 2016).

The proposition that "best practices" can be transplanted from one context to another assumes that the goals of education systems, the problems they face, and the desired solutions are universal. It ignores the desires and interests of communities and what and how they decide what their children should learn. What is "best" is, therefore, as Samoff (2021) notes:

.... necessarily local. Of course we can learn by observing what others do. But there are not and cannot be universal best practices, detached from their context.

Samoff (2021).

Further, a substantial body of evidence demonstrates that educational reforms and practices do not remain constant when transplanted to a new context. Transfer is followed by a process of local translation and as Cowen (2009) comments: “when it moves it morphs”. Accordingly, “best practices” are modified, recontextualized and often fail to achieve their stated goals. This was evident in the various attempts by the UK Government to introduce Mathematics curricula and pedagogy from Singapore and Shanghai into English schools; a move premised on the belief that this would drive English pupils to emulate the high levels of performance on PISA of pupils in those areas. Chinese curricula and maths teachers were brought to the UK; English teachers modified the curriculum to suit their own context and an independent evaluation concluded that the imported “best practice” resulted in no improvement in pupils learning outcomes (DfE, 2019).

The fifth assumption relates to the faithful use of PISA data by governments and is a variant of the second assumption on the faithful use of data by the OECD. This issue is especially pertinent in England, where policymakers have used pupil performance data extensively to justify reform in ways that are often highly selective or which distort the evidence. For example, in terms of selectivity, there has been a marked tendency for policymakers, the media and the network of policy advocates to focus on reports that are negative and serve to portray schooling in England as an educational dystopia in need of urgent and radical reform (Morris, 2012).

Even when England’s results show a slight improvement in its ranking or no significant change in the level of pupil performance, this has been characterized in the media and policy discourse as a decline in standards or, at best, stagnation. In contrast, there are reports that indicate relatively good performance in England, such as the 2007 TIMSS Report and the OECD Report (2013a).

Problem Solving in PISA 2012, receive comparatively little attention. The response in England to the 2013 PIACC Report (OECD, 2013b, online) was also illustrative of a tendency to interpret data selectively. England scored poorly on the tests of the literacy and numeracy skills of adults, and the OECD associated this with the impact of poverty and the low-skilled nature of much work in England. However, in the subsequent public discussion of the results by politicians and the media in England these factors were ignored and a range of other factors were proposed as the causes of the low performance. These included low curriculum standards, low standards of teaching, a dumbed-down curriculum and the absence of performance-related pay for teachers. The linkage in England between the specific policies promoted and the comparative evidence from which they are derived has been, at best, tenuous. For example, the reforms promoted in the 2010 White Paper (Morris, 2012) were primarily justified on the grounds that they were derived from the best practices of high-performing (i.e. primarily East Asian) systems. However, many of the policy initiatives – the establishment of Free Schools, multiple and shortened routes into teacher education, the recruitment of untrained teachers, and a national curriculum that was optional for academies and Free Schools – are not characteristics of those school systems in East Asia that topped the PISA league tables. Similarly, neither the PISA data, as interpreted by the OECD, nor the prevailing systems of school governance prevailing in East Asia provide a rationale to justify the form of school autonomy promoted in England since 2010 (You and Morris, 2015). Further, the direction of educational reform in many East Asian states is toward reducing the prevalence of the specific features (direct instruction, exam orientation and a focus on academic achievement) that English politicians admire and seek to emulate (Forestier and Crossley, 2014).

The final assumption, that the policy actions designed to improve PISA scores result in improvements to the quality of education, is fundamental, as the ultimate purpose of PISA is to improve the quality of schooling pupils receive and subsequently generate economic growth. We suggested above that by the OECD’s own analysis there is no evidence to indicate an improvement in educational outcomes, as measured by PISA scores. Instead, policy actions are justified by retrospective reference to what successful countries have done: these are then used to advocate the adoption of such interventions by less successful nations. Much of this “evidence” is often little more than axiomatic commentary, as is demonstrated by the following extracts from the.

PISA 2018 results report:

In 60 countries and economies (or four in five countries/economies), students who reported that the longest piece of text they had to read for school was 101 pages or more scored significantly higher on reading performance than those who reported 10 pages or less after accounting for students and schools’ socio-economic profile and students’ gender.

OECD (2021, online, p. 127).

Education systems with a higher proportion of students who were taught how to detect biased information in school were more likely to distinguish fact from opinion in the PISA reading assessment, even after accounting for country per capita GDP (OECD, 2021, online, p. 139).

In much the same way as the absence of particular factors is not noted in unsuccessful countries (see above), so by the time the following cycle is reported, three years have elapsed, and a robust follow-up to determine whether policy recommendations have resulted in the promised improvements is not undertaken. Instead, a new edition of glossy brochures, colourful charts and narrative commentaries is issued, glorifying the new successes and noting what it is that they have done to demonstrate improvement.

Emler et al. (2019) have identified a number of side effects or unintended consequences of PISA on school systems which serve to undermine their quality. These primarily arise from the introduction of policies designed to improve scores which result in a narrowing

of the curriculum and a focus on preparing for the test. Examples include: modify the curriculum content to better align with the test; increase the time allocated to areas tested in PISA by reducing the time allocated to other areas; train teachers to coach pupils how to pass the test; align existing systems of inspection and accountability to the test; and, introduce performance pay which links teachers' pay to improving pupils results in PISA subjects.

These actions illustrate [Goodhart's Law \(1975\)](#) which states: "when a measure becomes a target it ceases to be an effective measure" as the actions taken to achieve the target are designed to game the system and have no clear connection to achieving the ultimate goal, in this case improving the quality of education. Moreover, the "ultimate goal" is not evaluated in terms of the actions taken in response to earlier recommendations, so that the target is constantly moving.

The unintended negative consequences of such actions in education are evident in England, where successive governments have sought to use PISA data to further an already frenzied environment of serial educational assessment and reform. This "policy hysteria", characterized by short reform cycles and frequent policy switches ([Stronach and Morris, 1994](#)) took a "data turn" in 1997 when the then (Labour) education secretary David Blunkett declared,

The publication of performance data benefits parents and acts as a spur to improve performance. We will publish more such data than ever before.
[DfEE \(1997, p. 25\).](#)

Subsequent Coalition and Conservative administrations have enthusiastically followed in Blunkett's footsteps, and PISA has provided a rich seam of performance data which has been mined by Education ministers since-with one, Michael Gove, evangelizing on behalf of Andreas Schleicher during a visit by the latter to the UK:

[he is] a man I recently have described as the most important man in the British education system - but he could equally be the most important man in world education. ... in truth Andreas is the father of more revolutions than any German since Karl Marx.
[Gove \(2011, online\).](#)

While his junior minister, Liz Truss, faithfully repeated the economic messages underlying PISA:

The link between student scores in international tests and real GDP growth rates per head is growing stronger; doubling between 1960 to 1980 and 1980 to 2000.
[Truss \(2012, online\).](#)

Thus, there has been a neat alignment between the assessment ambitions of UK governments and the focus of PISA on measurable skills, especially in reading, mathematics and science, which has been reflected in a narrowing of the English curriculum to sideline Arts and creative subjects in favor of these same subject areas ([Johnes, 2017](#)).

Such actions may help to improve PISA scores but they undermine the requirement that schools provide a "broad and balanced curriculum" and it is unclear how they improve the quality of schooling. Whether or not it improves a country's ranking in the PISA League Tables is also less certain if the fallacy of composition operates and other nations adopt the same strategies.

More importantly, the focus on PISA scores results more generally in education policies being narrowly framed as solely designed to find solutions which will help improve those scores. The result is a form of policy tinkering designed to prioritize and resource activities directly related to influencing the target outcome. The focus on performativity ascribed to practitioners is mirrored by policy makers as they organize themselves around responding to targets, indicators, and evaluators. This has resulted in a focus on schools, curricula, teachers and leadership, while more complex and systemic issues of poverty, health, social deprivation which affect pupils' education, as well as more generic threats to humanity such as climate change ([Rapplee and Komatsu, 2020](#)) are ignored or marginalised.

A pattern has emerged: the OECD promotes policies based on claims which are "loosely coupled" to their own data; governments adopt those OECD recommendations and promote them to domestic audiences as "evidence based policy" and global "best practices"; and national governments develop their own policy stories which are tenuously linked to the evidence provided by the OECD. The outcome is often not the faithful use of evidence but rather that PISA emerges as an unlimited source of legitimizing data that can be used for asserting a multitude of potential policy stories. The OECD produces a vast quantity of data and an ongoing steady flow of documents, videos, social media posts and web-pages based on PISA. The sheer volume of material, and the regularity of updates - for example, the monthly "PISA in Focus" bulletins, billed as "a series of concise monthly education policy-oriented notes designed to describe a PISA topic" (OECD, online) - make it easy for policymakers to find global sources to support almost any policy initiative, which can then be described as "evidence-based" or be justified by reference to "world class" systems. Notwithstanding that PISA scores have not improved after two decades of adopting "best practices" the triennial cycle repeats itself as new crises and priorities are identified.

Where next?

We have analyzed the ways in which PISA operates as a new form of global accountability, and highlighted the weak foundations on which it is constructed, through an examination of its core assumptions. We identified four systemic issues, namely: a failure by the OECD to deliver on its promise to improve educational quality (as they define it); a conflict of interest arising from its mixing the roles of data collection and policy advocacy; the development by the OECD of a model of policy advocacy which claims agency for improvements but assigns failure to others; and, the use of PISA data by policymakers to deflect attention from deeper, systemic sources of disadvantage such as poverty and wider existential issues like climate change. We now briefly look to the future, and to where the PISA enterprise might next seek to cast its reach.

There are signs that the OECD is shifting its organisational discourse (Li and Auld, 2020). From its inception the OECD's core claim could be summarized as: *PISA accurately measures educational quality; high performance in Maths, Science and Literacy generates economic growth; high performers provide the source of "best practice" and transferrable policies.* More recent pronouncements suggest the OECD is now aligning itself with the UN's Sustainable Development Goals and adopting a more humanitarian discourse which can be summarized as: *we need to plan for an uncertain future (the fourth Industrial Revolution) which requires 21C/transversal/soft skills such as Creativity, Global Competencies & Well-being (not traditional/Legacy skills) and technology. The private sector and AI will play a central role in shaping these skills.*

Acknowledging this "future turn", Schleicher made the following statements:

the industrial approach to schooling, where children were educated in batches of age and all go through the same standardised and prefabricated curriculum and instruction", "hasn't really been conducive to nurturing the kind of creativity that we need in this age of accelerations. Whichever way you construct your list of 21st century skills, creativity will be at the heart of it.

Schleicher (2017).

And:

The kinds of things that are easy to teach are nowadays also easy to digitise and automate. In the age of artificial intelligence (AI) we need to think harder about how to develop *first-class humans*, and how we can pair the AI of computers with the cognitive, social and emotional skills, and values of people.

OECD (2018).

This is indicative of a move from "diagnostic expertise", whereby PISA has identified factors linked to success in high-performing systems, to a type of "prognostic expertise" in global governance, which "render[s] knowable what has not yet happened – the future" (Berten and Kranke, 2021). In this way, accountability is not only entirely decoupled from agency, as in current iterations of PISA, it is also predicated on an uncertain and unimaginable set of hierarchies and imaginaries which may exist in future.

A further set of challenges lies in the move to measuring non-cognitive competencies and including low- and middle-income nations in the PISA testing regime. Extending PISA to include poorer nations exacerbates the longstanding problems arising from using a universal metric across diverse cultures/contexts. As the OECD explained with reference to measuring Global Competencies:

The most salient challenge for the PISA assessment is that — through a single international instrument — it needs to account for the large variety of geographic and cultural contexts represented in participating countries ...

OECD (2018, online)

While developing the original, universal PISA tests of Mathematics, Reading and Science presented significant technical issues, these are now dwarfed by the more fundamental problems which arise from assuming that different cultures and societies have a common understanding of concepts such as "well-being" "creativity" and "Global Competencies" and that these can be measured through a standardized test. Studies have pointed to the ways in which the OECD's conception of a globally competent citizen appears to be a proxy for a globally mobile middle class knowledge worker (Gardinier, 2021). Goren (2020) demonstrates the deeply embedded nature of the challenge arising from the multiple understandings of the concept across cultures and its measurement by the OECD. She found that certain items, deemed sensitive by particular nations, for example on immigration, were required to be deleted from the OECD's Global Competence test; while one nation decided not to administer the questionnaire to a specific religious group (as it was contrary to their beliefs). Notwithstanding, the results and the associated comparative league tables were presented as if all participants had taken the same test, raising questions about its validity.

We have presented the PISA paradox; it is on the one hand the most successful and influential ILSA that is at the core of global educational governance; on the other hand it is constructed on weak foundations and has failed to deliver on its promissory claims

to improve the quality of schooling. The challenges it faces in maintaining its centrality on the global education stage require it not only to be seen to “respond” to a world which it tells us “is changing”; it also needs to be instrumental in helping to engineer that change, in order to capture it with metrics.

The purpose of this chapter is to provide a brief introduction to a very broad set of concepts: assessment, evaluation, and accountability. In doing so, it will be necessary to include the terms “measurement” and “testing” as part of the list; omitting them would leave a gap in one’s understanding of this area of education. It should be noted at the outset that these terms are overlapping, and that their definitions have evolved and changed somewhat over the past 50 years or so. Thus, one might find different definitions in older works on these topics. Finally, there really is not 100% agreement on what all these terms mean. We will try to provide the broadest consensus on their definitions and how they relate to one another. We begin with a series of definitions of terms, then a list of modifiers (adjectives) that have been used in relation to these terms, and then turn to an examination of the categories and sub-categories of these concepts, and how they are related. Following these definitions, we take a step back and look at the process of educational measurement in general—how it is accomplished, key characteristics, types of decisions made from measurements, and trends and innovations in testing. We focus in particular on formative and summative assessment at the student level, and large-scale assessments at the state, national, and international levels, as these issues are critical in the current educational climate. In order to simplify the text, we will often refer to instances of the entire enterprise as “assessment.” as it is the most popular term in usage today. But in looking at the field in general, “educational measurement” is probably a better umbrella term, and we use that occasionally as well.

Definitions of terms

Assessment

Of all the terms to be defined here, assessment is perhaps the most nebulous. It can mean a standardized test used to determine course achievement or how well a school is performing, or it can refer to a conversation between a teacher and a child who is

working on a personal reflection. Bloom (1969) provided an excellent definition of assessment, and although it is not by any means a standard definition, to us it captures the fundamental idea of what assessment is about. He argued that assessment concerns finding the fit between individuals and their environment. Such a definition would require taking into account the individuals and what they are doing/working on/learning at any given point in time. It would relate their efforts and abilities to where they were in their learning, what the learning environment was, and where the learners were headed. But over the past half century, the term “assessment” has been used in countless different ways and today can range from referring to national programs looking at school achievement across the years of schooling, or a learning story between a teacher and a preschooler (Carr and Lee, 2019). It has also become the term of choice for referring to any of a number of *approaches* to determining how well a student is learning. It appears to be a more palatable term than “testing” or “measurement.”

Evaluation

Evaluation has had a number of definitions over the years. House (1980) provided an excellent and simple description of evaluation: “Evaluation leads to a judgment about the worth of something.” (p. 18) House goes on to point out that this does not have to lead to action, although it often does. He notes that one can say that Caesar was a great general without doing anything about that. In education today, evaluation seems to be used primarily for looking at how well instructional programs (or schools, or teachers, etc.) are performing. It is typically assessed by looking at change in the intended outcomes (usually achievement) over time in comparison to a reasonable contrast. For example, how well did this new program do with these students in terms of growth over the year compared to students from the year before who didn’t get this program? Up until the mid 1980s, the term evaluation was often used to refer to evaluating student progress in learning. It was considered a broader term than testing; thus evaluation of student learning might include looking at essays, projects, presentations, etc. In 1971, Bloom, Hastings, and Madaus published the classic *Handbook on the Formative and Summative Evaluation of Student Learning*. “Evaluation” was the term of choice in referring to the determination of student progress and needs. They (Bloom et al., 1981) later published *Evaluation to Improve Learning*, which for us indicates that the term was still in popular use to refer to student assessment then. In 1988, Crooks produced a landmark review of work on classroom assessment activities entitled, “The impact of classroom evaluation practices on students.” Thus, the term evaluation was still in use to refer to this type of activity. Crooks, however, regretted the use of evaluation in the title. He would have preferred assessment instead of evaluation, as he thought that would generate a wider readership because people were using assessment more than evaluation (Crooks, personal communication, 2005). Thus, the mid to late 1980s appears to be when the shift in usage was realized.

Measurement

Measurement is a very broad term and relates to activities both within and outside of education. If we say that someone is six feet tall, that is a measurement. If we say that someone reads at the sixth-grade level, that, too is a measurement. One is based on physiology, the other on education. The fundamental idea behind measurement is that one defines a characteristic of an individual (typically) that is of interest and assigns a number to it that quantifies how much of that characteristic the individual possesses. It is inherently a method of quantification. Educational measurement is the process of obtaining information about the characteristics of students, schools, or educational systems. These characteristics may include knowledge, skills, abilities, as well as range of contextual descriptors, such as socio-economic status (SES), school climate, and others. The measurement process includes the development of protocols and tools for gathering information, procedures for collecting and analyzing the data, as well as evaluating the quality of obtained information. Furthermore, it concerns strategies for communicating scores to audiences, which may include policymakers, teachers, parents, and students, to name a few. Although the parties participating in the measurement process may vary, there are common requirements that are to be achieved in the educational measurement process, such as arriving at valid conclusions about students’ knowledge, skills, abilities, and other characteristics and, consequently, contributing to the improvement of teaching and learning.

Testing

Testing (in education as opposed to testing things such as tensile strength) is a process that typically yields a measurement. It is a specific form of measurement that uses a series of items or an essay (or essays) to ascertain where a student is with regard to some characteristic of interest. Thus, a test typically consists of a set of items (which is how testing experts refer to what is commonly known as “questions”) that are given to a testee. The testee attempts to get the right answers to the questions. Usually, a total score of the number correct is tallied and then either used directly or modified in some fashion to come up with a score. Sometimes the answers provided by the student are given scores other than simply right/wrong (such as a mark on an essay test). Modern testing, especially testing using computers, takes a slightly different approach to this process. A computer-based test usually estimates the testee’s ability after each item is completed, and new items are provided to the testee based on that estimate of ability (if a student gets an item wrong, an easier one is typically given next, and vice versa, until a stable estimate of ability has been obtained). As testing typically generates a scores (sometimes multiple scores on sub-scales—literal comprehension, inferential comprehension, vocabulary on a reading test for example), testing is generally considered to be a subset of the concept of measurement.

Accountability

If you were to ask a group of assessment and measurement specialists to list all the terms pertinent to what they do, many would leave “accountability” off that list. Accountability is more the stuff of political debates than it is of student learning and its assessment. Accountability is the process of determining whether a system is functioning as it should be and who should be held responsible if it isn’t. In education, this translates into the notion that children should be making certain levels of progress, and that testing/assessment can be used to determine whether those levels are being achieved. If not, then actions can be taken to determine how to make improvements. [Haertel and Herman \(2005\)](#) point out that accountability debates in education have been going on for at least a century in the United States. A movement toward accountability began at the state level in the 1970s and crystallized with the publication of “A Nation at Risk,” (National Commission on Excellence in Education, 1983). This report argued that student performance in the US had dropped precipitously over the previous several decades and that immediate steps needed to be taken to rectify the situation. Many observers saw this report and subsequent actions as a political effort to hold teachers accountable, with arguments for incentive—or performance-based pay regimens being called for.

Definitions of modifiers

Most of the terms defined above are used with modifiers to specify just what type of activity is being undertaken. There are many such modifiers that might be used; we pick what we believe are the most widely used here.

Formative/summative

Probably the most widely used modifiers for assessments are formative and summative. They come from the work of [Scriven \(1967\)](#) who used them to describe different purposes for evaluating educational programs. [Bloom \(1969\)](#) took the idea of formative and summative and applied it to use with evaluating (assessing) individual student learning. Formative refers to assessment that is primarily used for helping students learn. Formative assessment provides information to the student and the teacher that will help guide subsequent instruction. Summative assessment provides information that summarizes where students stand at a particular point in time with regard to their achievement. It is not concerned with improving that learning, but rather simply documenting the current state of affairs. Closely related to these terms is the popular nomenclature “assessment for learning” and “assessment of learning” ([Assessment Reform Group, 1999](#)). These terms have come to mean roughly the equivalent of formative assessment and summative assessment (respectively), but it should be pointed out that initially they were defined within a particular, student-centered philosophical framework.

Criterion-referenced/norm-referenced

The results that one derives from a test (often a quantification of student performance) are meaningless unless they are given a context for interpretation. For example, a score of 64, or 720, has no meaning unless a context is provided. Glaser and Nitko argued that we make meaning out of scores by referring them either to some standard of performance, or to a reference group (see, e.g., [Glaser, 1963](#); [Nitko, 1980](#)). A norm-referenced test (or, more appropriately, a norm-referenced interpretation of a test score) compares the score of an individual student to some reference group. This might be as simple as saying, “You got the best score in the class!”, or as sophisticated as saying, “This score is in the 83rd percentile of all children in the national norming group.” It allows the person looking at the score some basis for determining how good it is. A criterion-referenced score makes mean by referring the score to a preset standard. “You have passed your driver’s license examination” is an example of a criterion-referenced interpretation. There are no other people being compared with this score. This score passes. That is all one really needs to know. In education, criterion-referenced tests are often used to determine if a student is ready for some next level of instruction.

Combining the first two sets of modifiers, it is possible for one to have a criterion-referenced formative assessment, or a norm-referenced summative assessment (or other combinations as well).

High stakes/low stakes

The “stakes” of a test, evaluation, or assessment have to do with the consequences for those involved in the activity. The term is taken from the game of poker, where the stakes are the amounts that can be gambled. A high stakes test is one where there is substantial consequence, and low stakes the opposite. The consequences of the test or assessment may be different for different stakeholders in the assessment. For example, a statewide assessment may be very important for the school district in terms of rankings of quality or the possibility that the state will intervene in the school system if results are poor. Thus, at the district level, the stakes are high. But the assessment may have been given at the end of the school year and the results not provided until the next school year, and the results might not be used at all at the pupil level. Thus, the stakes would be very low for individual school children. This is important as it is well-known that the consequences, or stakes, of an assessment can greatly influence student performance ([Wolf et al., 1995](#)).

Large-scale

There is an entire category of tests and assessments that are referred to as “large-scale.” This means that the test is given to all the students (or a sample thereof) at some societal level (a nation, a state, internationally, etc.), and the results are used to talk about where the students are at a given point in time, or how much progress has been made since the previous assessment. Such assessments are usually professionally designed and administered, and carry high stakes at whatever level they are given. The National Assessment of Education Progress (NAEP) in the United States, or the Progress in International Literacy Study (PIRLS), given internationally. Obviously, assessments can be small scale as well, but that term is usually not applied.

Standards-based

Standards-based assessments are those which are based on a clear set of progressions/objectives/goals that are deemed necessary for the students who are being given the assessments. The argument here is that there is a knowable set of progressions that students move through on their way to literacy, numeracy, and other skills, and that these progressions are assessable. In theory, standards-based assessments allow for determining not simply whether students are progressing well, but whether larger entities, such as classes, schools, school districts, or even states and nations, are progressing satisfactorily. Many standards-based assessment programs have led to what is called “teaching to the test.” That is, since statistically equating test forms from 1 year to the next requires that the items on the test remain fairly similar, teachers become familiar with the nature of the items, and work with students on practice items of that type. This can lead to an increase in scores on that test, but not necessarily to other tests that measure the same content, but in a different form.

Minimum competency (basic skills)

Minimum competency testing, sometimes known as basic skills testing, is an idea that tends to go in and out of favor. In the 1980s there was a “back to basics” movement in the United States that saw a focus on what the minimum skills were that a student needed to succeed (at some level) in society—hence, minimum competency. Minimum competency testing is typically large-scale, standards-based, and high stakes, either for students or schools, or both.

Key characteristics of assessments

We turn now to the qualities that assessments need to possess. There are three key characteristics of educational assessments that must be taken into account at all times: validity, reliability, and fairness. Each one of these could be turned into a separate chapter, if not volume, but we will give the reader a flavor of what these concepts represent and offer *Standards for Educational and Psychological Testing* (AERA et al., 2014) as one of the most cited sources to glean additional information.

Validity

Validity may be defined as the soundness of interpretations and uses of assessment results. It is important to remember that the assessment results have different degrees of validity for different purposes and for different occasions. The *Standards for Educational and Psychological Testing* (2014) defines validity as the “degree to which evidence and theory support the interpretations of test scores for proposed uses of tests” (p. 11). This definition further emphasizes that validity is not only an attribute of the test; it describes what we intend to do with the results. We would take just a bit of an issue with the definition here as the validity of a measure is not actually the degree to which evidence supports that validity. A test could be valid without any evidence testifying to that status (One can be guilty of a crime even if there is not evidence of that guilt). But, that is a quibble.

The concept of validity went through a series of rather dramatic transformations over the past three-quarters of a century. So, in early editions of the *Testing Standards* (1954, 1974), validity was considered to be three-fold in nature. That is, *content validity* was thought to demonstrate how well the test covered the content area of interest; *criterion validity* compared scores of a test to external variables that measured the behavior or characteristic of interest; and *construct validity* was thought to describe the qualities that the test measures. Cronbach and Meehl (1955) considered construct validity as essential. In 1985, the testing standards revised their description of the three types of validity. Instead, they discussed them as three types of validity evidence, thus emphasizing that a unified concept of validity. Messick (1989) further emphasized a unified conception of validity as well as the importance of considering consequences of scores as part of the validation efforts. He defined validity as: “an integrated evaluative judgment of the degree to which empirical evidence and theoretical rationales support the adequacy and appropriateness of inferences and actions based on test scores or other modes of assessment” (p. 14). He discussed different categories in the validity inquiry—from convergent (i.e., whether test scores expectedly relate to other, similar measures) to discriminant (i.e., whether the test is unnecessarily highly related to measures to which it should not relate). Messick argued that construct validation should include testing plausible alternate explanations or meanings of the test score (Again, we would argue that validity is not a judgment about a measure, but rather an inherent characteristic of the measure itself for any given use).

A more recent conception of validity was introduced by Kane (2006) who offered a more pragmatic approach to defining and establishing validity. He proposed that validation comprises two kinds of arguments. The first one is an interpretive argument that “lays out the network of inferences and assumptions leading from the observed performances to the conclusions and decisions based on performances” (p. 23). The second one, called validity argument, provides an evaluation of the overall coherence of the interpretive argument and the plausibility of assumptions. He defined validation as the process of evaluating the plausibility of interpretations and uses, and validity as the extent to which accrued evidence supports suggested uses and interpretations. We would like to refer our reader to Kane (1992, 2006) and to an excellent article of Moss (2013), both of which cover the topic of validity in great detail.

Reliability

Reliability is defined as the consistency of assessment results across replications. That is, would we expect to get similar results if an assessment (or a highly similar form of it) were given to the same students a few days after the initial assessment? Are the results consistent over time? One might think of reliability as the degree to which a measure correlates with itself on two different administrations. A complementary concept, measurement error, focuses on how much a score may vary on a subsequent administration. In education contexts, the sources of measurement error may include items, raters, or occasions. There are numerous indices for reporting reliability, including reliability coefficients, generalizability coefficients, standard errors of measurement, and information functions, among others. The indices are used differently depending on a test theory that is used as a basis.

Reliability may be considered to be a subset of the concept of validity. If a measure doesn’t provide consistent results from one administration to the next, how can it provide valid results? The level of reliability needed in a measure depends on its uses and stakes. For example, reliability is critically important when the consequences of test use are high stakes. In making decisions about classifying a student with a particular type of special need, one would want the reliability to be very high. For looking at the efficacy of an instructional program, reliability at the individual student level would be less critical.

Fairness

The third key feature of educational assessment is fairness. The essence of fairness is that if two students have the same ability with regard to what is being measured, then they should get the same score irrespective of race, ethnicity, gender, or other characteristics. Tierney (2016) breaks this down into three features of fairness. The first is that educational assessments must be democratic, inclusive, and supportive of student diversity. This requires assessment designers to consider ensuring that some students are not in any way favored over others. Specifically, when student characteristics, background, and abilities (e.g., language spoken at home, gender) are not relevant to the construct being gauged, then they logically should not influence the scores resulting from the assessment. The second characteristic relates to stakeholders’ *perceptions* of fairness. When students and stakeholders perceive an assessment as fair, the buy-in and engagement is more likely, as opposed to superficial completion of the assessment. Finally, the pedagogical imperative is of key importance to fairness. Educational assessment has been seen as a social process that may increase opportunities to learn (Moss et al., 2008). The fairness of classroom assessment, regardless of purpose, is affected by classroom relationships and interactions, which in turn influences the learning environment. This loop can be scaled up from individual classrooms to larger systems, based on the assumption that all educational assessments should ultimately inform teaching and learning (Tierney, 2016).

Purposes of educational assessment and types of educational decisions

Assessment activities may focus on educational functions and outcomes at various levels. As noted above, assessments may be used to gather information at the country, state, institutional, program, and individual levels, to name a few. At higher levels, assessments typically incorporate aggregated individual data, whereas at the individual level, the collected data reflect student performance and learning or teachers’ performance indicators (Darling-Hammond et al., 2013). Assessment data from the various levels can be reported in both aggregate and individual level. For example, student graduation data can be reported and analyzed at individual, district, as well as state and national levels (Brookhart, 2011).

Assessments may also be differentiated depending on different types of decisions that rely on the outcomes of educational assessment. Depending on the type of decision, different tools and assessment procedures will be used. For example, assessment can be used to inform *selection decisions*, where school and university admissions consider student scores on tests as a condition for selection. One of the important considerations of this type of decisions has to do with its predictive value. In other words, candidates’ performance on these types of assessments should relate to their success in the program for which they were selected (Dahlke et al., 2019).

A related type of decision that is based on results of educational assessment is *placement decisions*. For example, tests that screen students into advanced, gifted, and talented programs represent placement decisions. The difference between selection and placement is that in the former case, students may be rejected from the institution, whereas in the latter case their elimination is not possible. Students are placed into appropriate educational levels that are likely to result in their improved achievement (Lakin, 2018).

Whereas a single test may be enough to complete selection and placement process, *counseling and guidance* relies on a suite of educational assessments (Chandler et al., 2018). The types of different tools that can be used for this purpose may include interviews, interest inventories, aptitude tests, and achievement batteries. The outcomes of these assessments are discussed with the students during a series of counseling sessions.

Certification decisions represent yet another category, with teacher certification being one of the most illustrative examples. Some states in the US employ paper-and-pencil tests to assess preservice teachers' knowledge. These tests may gauge content knowledge, pedagogy, and professional knowledge. Other states use portfolio assessments or classroom observations to certify teachers (Parfitt and Rose, 2018; Gitomer et al., 2021).

Instructional decisions are probably the decisions most frequently taken in any educational context. These are ongoing assessments that a teacher makes to evaluate students' current level of performance and share information on how they can achieve their desired level of performance. These assessments are also used to provide information to the teacher about how well the students have mastered a task in order to adjust instructional activities (Black and Wiliam, 1998; Brookhart, 2011). These types of assessments are typically referred to as "formative" and are juxtaposed with "summative" ones. We devote the next section to this dichotomy.

Formative and summative assessment (and assessment for learning)

For teachers, the most important aspects of assessment to understand are the ideas of formative and summative assessment, and the closely related ideas of assessment *of* learning and assessment *for* learning. These concepts were introduced above, but they are so important that we elaborate on them here. When Bloom first developed his notion of mastery learning theory (Bloom et al., 1971; Guskey, 2007), he incorporated formative assessment into the theory. He argued that after a relatively brief period of instruction, a short test should be administered to students to see how well they were doing. This test would only be used to guide specific additional instruction for those who needed it, and not be included as part of a grade. In Bloom's conceptualization, the information was primarily for the use of the teacher. Over time, the focus of formative assessment has turned to providing information and guidance on improvement directly to the student. In the mastery learning approach, students would proceed through the course of instruction, and at the end, they would take a summative assessment based on the entire course, and that assessment would be used for a final grade. But summative assessment could also include statewide, national, or international assessments that are used to assess the progress of large groups of students.

The distinction of formative and summative assessment has become widespread throughout education, and formative assessment, along with instructional feedback, is an essential component of teaching almost worldwide (Lipnevich and Smith, 2009, 2018; Kluger and DeNisi, 1996; Ramaprasad, 1983; Sadler, 1989; Wiliam, 2011, 2013). The notion of "assessment for learning" (as opposed to assessment of learning) has become as popular, if not more popular than formative assessment. This notion was developed by the Assessment Reform Group in the United Kingdom in 1989. They proposed the following set of characteristics for assessment for learning that they argued would lead to better instructional practice:

- it is embedded in a view of teaching and learning of which it is an essential part;
- it involves sharing learning goals with pupils;
- it aims to help pupils to know and to recognize the standards they are aiming for;
- it involves pupils in self-assessment;
- it provides feedback which leads to pupils recognizing their next steps and how to take them;
- it is underpinned by confidence that every student can improve;
- it involves both teacher and pupils reviewing and reflecting on assessment data (Assessment Reform Group, 1999, p. 7).

The difference between assessment for learning and formative assessment was in the emphasis placed upon a philosophical commitment to child-centeredness that is found in the assessment for learning conceptualization. It must be said, however, that assessment for learning and formative assessment are used pretty much interchangeably today.

Evaluation and accountability through large-scale assessments

At national and systemic levels many countries have well-designed accountability systems in place, such as large-scale assessments. That is, assessments at the population level are used to monitor and evaluate different educational systems and how well student populations emerging from these systems do at the national level and in cross-country comparisons. However, there is frequently a disconnect between the national agenda and classroom practice. Generally, large-scale assessments do not feed into individual schools, let alone individual classrooms, because they are not designed for this purpose. However, they can potentially be used to compare different school types within a country if the drawn school samples are large enough. Let us explicate the nature of large-scale assessments (LSAs).

Different LSAs show some variation in their aims and frameworks. NAEP, TIMSS and PIRLS are more driven by countries' school curricula (Mullis and Martin, 2015, 2017); NAEP Large-scale assessments (LSAs) are comparative educational surveys that are widely used to inform policy makers and provide large data bases for educational researchers. They compare skills, knowledge, attitudes, and behaviors across different populations and subpopulations of interest. The focus of these assessments is on group-level scores in contrast to large-scale testing programs that aim to assess individuals. This is reflected in the test and sampling design of

LSAs as well as in the reporting of results. LSAs have grown and expanded over the past decades (since the late 1950s) to include a broader range of skill domains and populations, and to better meet the questions posed by policymakers and researchers worldwide (Kirsch et al., 2013). We next provide a general overview of the most important aspects of LSAs; more detailed information on each aspect is provided in Khorramdel et al. (2022).

Purpose and policy relevance

The overall purpose of LSA is to provide policymakers and researchers with valid data and meaningful group-level information about populations and subpopulations of interest with regard to skills, knowledge and behavior and how these relate to educational, economic and social outcomes. The focus is especially on skills that “contribute to the prosperity of nations and economies and to better lives for individuals in those nations” (Kirsch et al., 2013). LSA can be utilized for monitoring educational effectiveness and can help develop ways to improve the quality and equality of education worldwide. With their rich data bases, LSA provide comparative data about countries’ student achievement in relation to key home, school, and classroom variables (Mullis and Martin, 2017). Thus, they enable researchers to examine the relation of students’ proficiencies to their contexts for learning. They also allow for monitoring the effectiveness of a country’s educational system compared to other countries and own expectations, and for measuring progress over time (trends).

Examples of large-scale assessments

LSAs can be roughly categorized into national and international assessments. They assess either student or adult populations of different age groups or school grades within or across countries. There are also regional assessments which compare populations within a particular geographical region. The National Assessment of Educational Progress (NAEP), conducted by the National Center for Education Statistics (NCES), was one of the first of its kind and has assessed elementary and secondary grade students across the US since 1969. A cross-country feasibility study that was conducted for NAEP at the Educational Testing Service (ETS) in the 1980s (Beaton and Barone, 2017; Kirsch et al., 2013), paved the way for other LSA that followed. Some of the most prominent LSAs are the Trends in International Mathematics and Science Study (TIMSS) and the Progress in International Reading Literacy Study (PIRLS). They are both conducted by the International Association for the Evaluation of Educational Achievement (IEA) and the TIMSS & PIRLS International Study Center. These assess students at grades 4 and 8 in over 60 countries. The Program for the International Student Assessment (PISA) and the Program for the International Assessment of Adult Competencies (PIAAC) are both conducted by the Organization for Economic Co-operation and Development (OECD). Here the focus is on 15-year-old students in over 90 countries and 16–65-year-old examinees in over 40 countries, respectively.

Some assessment frameworks¹ focus on school-related skills while others are interested in skills needed to meet real-life challenges at home, work and in the wider community (PISA 2022 Assessment and Analytic Framework²; OECD, 2021). However, the designs and methods utilized in LSAs, as described below, are very similar.

Domains and constructs

The core achievement domains in most LSAs are reading and literacy, mathematics and numeracy, and science. Each domain consists of a content dimension, specifying the subject matter to be assessed, and a cognitive dimension, specifying the thinking processes to be assessed. This leads to different subdomains for each domain. Whereas international reporting and comparisons usually focus on results in the overall domain (e.g., reading), information about subdomains (e.g., locate, understand, and evaluate information) is available in the database as well (note that subdomains are generally highly correlated).

In addition to the listed core domains, NAEP also provides measures for arts, civics, economics, geography, US history, technology and engineering, and writing. TIMSS and PIAAC provide additional measures in different types of problem solving (problem solving and inquiry as part of mathematics and science, and problem solving in technology rich environments and adaptive problem solving, respectively). PIRLS, PISA and PIAAC also measure digital reading, and PISA offers the measurement of financial literacy as well as the option of a new innovative domain in each cycle, which is only assessed once, such as collaborative problem solving, global competence, creative thinking, or learning in the digital world.

LSAs not only collect achievement data but a large set of policy relevant background or context variables through student, parent and school questionnaires as well. These include home and school contexts for teaching and learning, students’ home background, school and classroom resources, teacher and teaching quality, and equity. Context variables can be used to examine and understand group differences in cognitive proficiencies and achievement, and can be related to other external variables like social economic status or school and teaching systems. They also have potential to be leveraged to maximize educational outcomes (Lee and Chen, 2019; Lee and Stankov, 2018).

Measurement characteristics and design considerations

Establishing comparable achievement and contextual scales across populations is an important goal of international large-scale assessments and the basis for group comparisons and the reporting of trends (cf. Khorramdel et al., 2020a,b). This is achieved through high standards in instrument development, specific sampling and test design considerations, standardized data collection, the use of item response theory (IRT; Lord and Novick, 1968), and population modeling (Mislevy et al., 1992; von Davier et al., 2006, 2009; von Davier and Sinharay, 2013). To enable the reporting of trends, LSA are administered in cycles. Depending on the subject domain, NAEP is administered every 2 or 4 years; TIMSS has a 4-year cycle; PIRLS has a 5-year cycle; PISA is administered every 3 years; and PIAAC follows approximately a 10-year cycle. Each LSA cycle is preceded by a field test for evaluating the quality of the instruments, procedures and building capabilities (e.g., preparing countries for the main assessment).

LSAs are based on two important sampling considerations: population and domain sampling (Beaton and Barone, 2017). Population sampling refers to the selection of representative samples with similar distribution of characteristics like in the defined target population. The aim is to provide reliable and accurate measures at the population and subpopulation level. The sample has to be large enough to provide estimates with sufficiently small standard errors, yet small enough to be cost effective. Hence, the goal is to select the smallest sample size that will meet the defined measurement standards (Beaton and Barone, 2017). Domain sampling refers to the makeup of the test itself. The achievement of a valid representation of frameworks and constructs would require a large number of items for each assessed domain, resulting in more items than can be possibly taken by one test-taker. Therefore, LSAs make use of sampling designs (Messick et al., 1983; von Davier et al., 2006; von Davier and Sinharay, 2013) that reduce the burden for individual students and the time and costs for participating countries. Each student is assessed with only a subset of the available items while the overall design ensures that the complete item pool is administered at the national level.

Thus, LSAs do not provide reliable achievement estimates at the individual student level, but allow for reliable estimates at the group and country level (von Davier et al., 2006, 2009; von Davier and Sinharay, 2013). Since these are group-level estimates, they cannot be used or interpreted like individual test scores. More information on this work can be found in Yamamoto et al. (2013, 2019) and the PISA 2018 technical report.

Trends and innovations

Providing trends over time in an everchanging world is one of the biggest challenges of LSAs. As the world around us changes, requiring our skills to evolve with it, LSAs strive to evolve and improve with each assessment cycle. However, the reporting of trends is based on comparable scales over time and significant changes from one assessment cycle to the next can break the trend. Therefore, changes in content or methods have to be made gradually to ensure the trend measure while, at the same time, moving into the future.

One of the most important recent changes in LSAs was the transitioning from a paper-based to a largely digital-based administration. This introduced the possibility of assessing new skills through innovative and interactive tasks and item types, as well as the advancement of new methods for analyzing LSA data (von Davier et al., 2019). Adaptive test designs can accommodate the participation of countries with a larger variation in average student proficiency (Yamamoto et al., 2018a,b, 2019) and the use of automated scoring for open-ended response items can improve the scoring accuracy (Sukkarieh et al., 2012; von Davier et al., 2022; Yamamoto et al., 2017; Zehner et al., 2016).

The expansion of LSA to include a wide range of participating countries and populations within those countries, as well as to assess constructs beyond typical academic domains like reading, mathematics, and science reflect the “growing recognition of the need for lifelong learning as a tool to succeed in rapidly changing economies” (Kirsch et al., 2013).

Reporting of results

Results of LSAs are reported at the international and at the national level. At the international level, the data bases, technical documentation, and policy related reports (including cross-country comparisons) are available on the websites of the organizations that conduct these LSAs (e.g., NCES, IEA, TIMSS & PIRLS International Study Center, OECD). At the national level, each country produces detailed reports on their own country-level results (including the comparison of subgroups and samples within countries and descriptions of educational systems).

Results are reported with regard to different benchmarks (e.g., in TIMSS and PIRLS) or proficiency levels (PISA and PIAAC) with descriptions of each benchmark and proficiency level. International databases, international reports, and national reports are usually released to the public at the same time and covered by the media in each country. The full transparency of the data and results are instrumental in the impact of LSAs on educational policies and their use in educational research.

Conclusion

Our goal with this chapter was to offer a broad overview of a number of concepts that are discussed under the large umbrella of educational assessment such as measurement, testing, evaluation and accountability. We discussed these and related concepts in the context of high versus low stakes assessments as well as individual-based versus group-based assessments. We also described

criterion and norm referenced assessments, standards-based assessments, formative and summative assessment, and presented an introduction into large-scale assessments. Different types of assessments provide a vast amount of information for policy makers and stakeholders and, when used properly, can create opportunities for everyone involved in the educational process. The field of assessment, evaluation, and accountability in education is evolving, and we will continue to harness the power of these assessments and processes to inform decisions that help learners of all levels and educational contexts to achieve their highest life potential.

Introduction

Consider a typical primary grade classroom. To an untrained observer, such a classroom may seem quite chaotic as the teacher shifts from one activity to another and the students shift from quiet attention to boisterous action. Nevertheless, underlying this apparent chaos is a complex learning environment in which the teacher is continually observing, monitoring and assessing students' learning to direct their teaching and support students' learning. Researchers and educators have long understood the value of these actions within the context of teaching; however, over the past 25 years, there has been an even greater emphasis on the potential of such assessment methods to enhance both teaching and learning (Andrade and Brookhart, 2016; Assessment Reform Group, 2002; Birenbaum et al., 2015; Black and Wiliam, 1998, 2006; Chappuis et al., 2012; DeLuca et al., 2018; Stiggins, 2005).

The concept of formative assessment or "Assessment for Learning" has come to represent the critical shifts in the role of assessment as an integral part of classroom learning (e.g., Assessment Reform Group, 2002; Birenbaum et al., 2015; Brookhart, 2011; Laveault and Allal, 2016; Stiggins, 2005). Within the framework, both the teacher and the students are active users of ongoing assessments that are integrated, formally and informally within the interplay of teaching and learning. There is strong evidence that these practices have the potential to positively impact students' educational outcomes (Flóres and Sammons, 2013; Wiliam et al., 2004). In response, teachers across international jurisdictions have been encouraged to implement comprehensive formative assessment practices to better support students' learning. These calls are explicit in national and board policies (e.g., Ryan and Feller, 2009) and classroom assessment research (e.g., Klinger et al., 2016; Laveault and Allal, 2016; Stiggins, 2005; Wylie and Lyon, 2015), and standards of practice (e.g., Brookhart, 2011; Klinger et al., 2015; Ndalichako, 2013). In support, researchers and policymakers have developed guidelines, principles and models to help teachers understand and implement these current assessment conceptions. Despite these supports, research continues to show that teachers struggle to interpret assessment policies and implement practices aligned with contemporary formative assessment notions (Bennett, 2011; DeLuca and Klinger, 2010; DeLuca et al., 2012; Laveault and Allal, 2016).

While there is little debate regarding the potential of formative assessment practices to be a powerful classroom "tool," there has been much debate with respect to developing teachers' capacity to effectively implement these practices (e.g., Bennett, 2011; DeLuca et al., 2012; Laveault and Allal, 2016; Kingston and Nash, 2011; Klinger et al., 2012). While some have focused their critiques on the lack of empirical evidence regarding the effectiveness of formative assessment to impact educational outcomes, (e.g., Dunn and Mulvenon, 2009; Kingston and Nash, 2011), the greatest concerns tend to focus on the challenges of developing teachers' assessment competence. This focus on teachers' competence has highlighted that principles and models alone are insufficient to create the necessary changes in classroom assessment (Wylie and Lyon, 2015). Rather, there is a need for integrated and focused professional learning initiatives that enable teachers to collaboratively explore new assessment practices (City et al., 2009; DeLuca et al., 2015; Flóres and Sammons, 2013). In summarizing their systematic review of assessment for learning and efforts to support its implementation, Flóres and Sammons (2013) identified a series of strategies and practices that would support relevant and effective professional learning. These included "an atmosphere in which teachers are expected to watch others in action—to actively support peer observation" (p. 2), and professional learning opportunities that enable teachers to develop a "flexible and deep understanding" (p.

2) of formative assessment approaches rather than the accumulation of techniques (see also DeLuca et al., 2015, 2019; Guskey, 2000; Klinger et al., 2016).

Of critical importance for our work is the recognition that the professional context in which teachers are working may have large impacts on the success of any efforts to develop teachers' assessment competence and skills (Birenbaum et al., 2015; Flóres and Sammons, 2013). And as Flóres and Sammons (2013) note, these challenges are even further exacerbated "in those contexts in which the ideal conditions observed in research are not given" (p. 4). It is within these "far less than ideal conditions" for professional learning and classroom practice that our work resides. With support from the Aga Khan Foundation and Global Affairs Canada, our work and research in the East Africa region was an attempt to enhance the formative assessment practices of rural primary teachers in this region. Our research not only addressed the paucity of information about classroom assessment in rural East Africa (Ndlichako, 2004, 2013; Rea-Dickins, 2006; Wachira and Klinger, 2017) but also provided an empirical evidence-base on how effective formative assessment practices could facilitate students' learning and promote classroom inclusion and equity within this context.

The research and learning context

As developing countries, the nations of East Africa are typically characterized by one or two large metropolitan centers with substantial portions of their populations living and working in rural communities. As a result, there are substantial differences in terms of access to educational resources, training and opportunities. When asked to consider a typical primary classroom, it is unlikely that the generated image was one in which there are between 140 and 200 children in a room with a single teacher, and that the classroom lacks electricity, has a single blackboard and there are seats for less than half of the children. Nevertheless, such an image could easily be observed of a teacher working in rural eastern Africa. Using Tanzania as an example, as this is where the majority of our work was completed, concerns have long been raised about the quality of primary education in the region, and several policies and reforms have occurred over the years to address these concerns (e.g., Magidanga, 2021; Ministry of Education and Vocational Training, 2013, 2015; Tanzania Institute of Education, 2005; Twaweza-ni sisi, 2015; USAID, 2013).

Similar calls for classroom assessment reforms can be traced back to 1995. The 1995 Tanzanian Education and Training Policy (ETP) acknowledged that teachers in East Africa needed to strengthen their assessment skills to provide quality education (URT, 1995). The ETP further highlighted the need to introduce courses in assessment and evaluation. Yet the primary focus of these subsequent teacher education courses was on the administration of classroom tests and examination and measurement theory and research (Meena, 2009; MOEC, 1996a,b), rather than on the development of skills and competencies of using assessment as part and parcel in classroom teaching. As Ndlichako (2004) argued, this likely contributed to teachers' tendency to largely rely on the use of tests and examinations to evaluate students' learning (see also Halai et al., 2022). Since 2013 the Primary School pre-service teacher training in Tanzania has been managed and coordinated by the National Council for Technical Education (NACTE). Primary school teacher education programs include modules on assessment, measurement and evaluation. Given that the majority of teachers in the rural regions received their teacher education before this time, and the lack of professional development available to teachers in rural communities, it is unlikely these teachers have developed sufficient assessment competence to effectively enact AfL practices (Halai et al., 2022). As those familiar with formative assessment attest, the lack of assessment education poses challenges, especially when considering the crucial role of teachers' assessment practices for teaching and students' learning (Brookhart, 2011; DeLuca et al., 2012; Kingston and Nash, 2011; Klinger et al., 2012).

Methodology

The foundations for our work are based on three pillars for supporting teachers "professional learning and influencing their subsequent instructional practices. First, as described above, advances in our knowledge about formative assessment reflect a valuable pedagogical practice to support teachers' efforts. Second, professional learning interventions for teachers are more successful when they include an on-site, sustained effort, supported by peers and knowledgeable experts. Lastly, professional learning initiatives must be responsive and aligned with the cultural and environmental context in which teachers and students work.

Our collaborative research was conducted in Western Nile, Uganda and Southern Tanzania. The study was structured as follows: first investigated teachers' classroom assessment conceptions and practices, and subsequently developed and implemented a contextually relevant, professional learning "intervention" to strengthen teachers' assessment capacities. Instructional Rounds (IR) has been identified as a powerful professional learning approach that combines long-term, professional learning guided by experts with teacher practice and peer observation (e.g., City et al., 2009; DeLuca et al., 2015; Marzano, 2011). IR was ideal for strengthening teachers' assessment capacity as it builds on teachers' current skills in a manner that teachers find highly supportive and non-

Fig. 1 The stage 2 instructional rounds process.

threatening (see Fig. 1). Importantly, the inclusive nature of IR and the supportive professional learning environment it creates led to the development of exemplary assessment practices, Assessment Guidelines for early literacy and numeracy development and persuasive policy briefs based on our findings (Wachira et al., 2017).

We used a multi-method approach to provide deeper understanding and greater explanatory power, using a progressively focused design with three inter-related stages. In the first stage, we used a mixed-methods survey ($n = 366$) and an ethnographic study (40 teachers and head teachers participating in Stage 2) to ascertain early years teachers' current assessment knowledge and practices. Our primary focus was to determine teachers' current conceptions of assessment and the assessment methods and strategies teachers used in their classrooms. Stage 2 comprised of a 9-month longitudinal professional learning, IR "intervention" to strengthen teachers' assessment capacities through a collaborative method to support students' and teachers' learning (Appendix 1).

We used a two-phased approach, combining three-day teacher workshops with centralized days in which teachers observed each other within their schools and with other schools in the project implementing a recently discussed assessment strategy, followed by an expert-led debriefing session. Teachers subsequently practiced these strategies in their classrooms. The process was repeated on a bimonthly basis. Teachers selected specific AFL learning goals and supported one another in planning for and implementing these goals to support teaching and learning. Through peer observations and assessment expert debriefing, teachers collaboratively engaged in learning about AFL within their local teaching contexts. Through structured activities during the workshops, teachers documented their assessment experiences and identified empirical "assessment episodes" and samples collected during Stage 2. These contextually relevant materials were then used to develop Teachers' Assessment Guidelines with high curriculum validity. The assessment guidelines were developed both in English and Kiswahili so that they could be easily accessible to teachers in both the Tanzanian and Uganda contexts.

Results

The first stage of our research provided critical information regarding teachers' assessment practices, and enabled us to better focus our efforts in subsequent stages. Over 80% of the teachers associated assessment with tests. They considered assessment to be individual paper and pencil written tasks given to students at the end of instruction and subsequently assigned a grade. For these teachers, assessment was a formal written activity done with the intention of grading students. A much smaller number of teachers viewed assessment as being both formal and summative, although it was associated with measuring students' increasing proficiency as instruction progressed. This seems to suggest that teachers' conception of assessment was more focused on performance rather

than on the substance of learning. Assessment was also understood as a diagnostic tool used either at entry to different classes, a new topic or at the beginning of the lesson to find out the students' knowledge and skills before engaging them in learning. While this can be considered one aspect of *AfL*, the vast majority of the teachers only used this information to measure students' attainment rather than as a tool to influence teaching and learning.

Our findings further indicated that more than 87% of the participating teachers had never received any professional development on assessment. Coupled with our review of teacher education materials which found that less than 5% of their education addressed matters of assessment, these teachers would not have been familiar with the growing body of research related to formative assessment and would not have yet obtained the necessary assessment competencies to effectively use *AfL*.

Building an *AfL* culture through questions

The results obtained in Stage 1 demonstrated that teachers considered assessment as being separate from learning. They believed that learning came first, to be followed by a formal, graded assessment. In contrast to these expressed views of assessment, our classroom observations revealed that all of the teachers consistently assessed their students through oral questions. When asked if this was an example of assessment many were hesitant to call it such, and as one teacher insisted *"this is too informal, and has no record."* Regardless, these observations suggested that questioning practices could serve as a doorway into *AfL* as it would build on practices already in place. Admittedly these questioning practices, as with the other assessment activities we observed were very teacher-centric. Teachers' questions tended to solicit low-order thinking responses, offered little feedback to probe or enable students to reflect on their learning, and students rarely directed any questions toward the teacher or their peers.

In contrast to the formality and summative nature of teachers' assessment practices, they did recognize that assessment could be used to improve teaching and learning, along with the more formal evaluative purposes which would keep students and teachers accountable. While we rarely observed this in practice, it once again highlighted an opportunity to enhance these teachers' assessment capacities.

As identified in the first stage, teachers' questioning practices provided an opportunity to introduce the foundations of *AfL* while also enhancing their assessment practices. While questioning may not be a principle of *AfL*, effective questioning practices can provide opportunities for rich feedback and student engagement, both of which are fundamental to *AfL*. The intervention began with a workshop that oriented teachers to three major questioning practices (e.g., Poehner and Rea-Dickins, 2013). Subsequently, IR sessions provided opportunities for teachers to visit and observe each other's developing questioning practices, and to debrief and analyze these experiences. The interventions focused on three major aspects of questioning: (1) high-order thinking questions; (2) wait time; and (3) Student questions, self assessment and peer assessment. Teachers were introduced to Bloom's Taxonomy and its use to design questions at higher levels of thinking. As a next step, teachers were encouraged to design questions before class to ensure the questions would focus on the learning objective and to make sure the questions solicit high-order thinking. Teachers were also taught to give much more wait time after asking questions, from 6 to 10 s before asking for a response. Lastly, teachers learned to provide opportunities for students to ask questions to their teacher and peers. To accomplish this, teachers not only had to build students' confidence to ask questions but also equip students with questioning and reflection skills.

Building assessment competence

The IR sessions provided opportunities to shift practice, and these were supported by workshops that helped to advance teachers' knowledge, skills and competence in using various *AfL* techniques such as learning intentions, feedback, and assessment development. Our focus was to demonstrate the important connections between learning and assessment. Teachers were first encouraged to shift from "learning objectives" to "learning intentions" in order to place a greater emphasis on the process of learning rather than the end product. From here, the value of sharing these learning intentions with students was introduced, along with the use of success criteria as a strategy to monitor progress toward the learning intentions.

If students are to efficiently progress toward the achievement of learning intentions, they must receive learning focused feedback and assess their learning. The types of feedback we promoted were in contrast to the typical feedback we observed in Stage 1 in which the feedback teachers gave to students was short, unhelpful or unclear, and sometimes even irrelevant and demoralizing. The workshops provided teachers with the knowledge and skills to make the shift toward using feedback to support learning. Those familiar with *AfL* know that a key component of *AfL* is in empowering students to take a role in understanding and communicating their progress. Learning is enhanced when students are able to use feedback and also self assess their own progress to assume responsibility and independence. During the workshops, we explored the use of having students ask questions of themselves such as: "Do I understand?" "Do I need help?" "Have I met the learning intention?"

Lastly, workshop sessions focused on the development of teachers' skills in writing assessment items. The workshops sought to create an awareness of different types of assessment tasks under the general categories of selected and constructed response items.

The advantages and challenges of each were discussed in an effort to make teachers aware of the implication of using different assessment items. Teachers were first provided with an opportunity to develop items which were then collaboratively analyzed for item structure, suitability and validity.

The assessment guidelines

Professional learning projects last for only a given time period and have a direct impact on the limited number of those able to participate. Hence a critical component of our work was to document our collective learning and use this to develop guidelines that both teachers who were in the project and others in the region could use to enact contextually relevant AfL practices. These guidelines are intended for use by teachers in a variety of curricular areas and across grade levels, along with head teachers and school principals who have responsibility for supporting the professional practices of their teachers. Further, the guidelines provide a strong foundation for professional learning in classroom assessment, both for pre-service teachers and for teachers who are currently working in schools. The *Classroom Assessment Guidelines* document the experiences of teachers to highlight, with examples, AfL practices used by those who participated in the Instructional Rounds and workshops. As a result, the development of the *Classroom Assessment Guidelines* was a result of collaborative efforts between researchers and teachers. This collaborative process enabled us to translate current knowledge about effective classroom assessment into a narrative that was based on contextually applicable classroom examples, and reflected the developing, classroom assessment practices of early years' teachers.

Our intention here is not to reproduce the *Classroom Assessment Guidelines* published by Wachira et al. (2017) but rather to highlight the format and structure that resulted from our collaborative efforts. The Guidelines were organized into four broad components: (1) Foundations of Effective Assessment; (2) Power of Questions; (3) Creating Assessment Items; and (4) Student Led Assessment. Within each component, a series of narratives described a specific formative assessment practice that the project teachers implemented. The narratives were based on our observations and the descriptions provided by participating teachers. Along with each narrative, key aspects of the practice were identified, extensions to the practice provided, and points to remember listed.

Each component begins with a brief definition and purpose of the component to introduce the assessment concept under discussion and highlight its value and potential impact on students' learning. The section is then followed by various types of assessment under the specific component. For example, the section on student led assessment is then followed by a specific focus on self assessment, peer assessment and group assessment. These specific areas of focus are represented by a narrative describing an assessment episode adopted from one of the actual classroom lessons observed. To capture its substance teachers were interviewed after the class so as to capture their thoughts about the assessment mode they used: purpose, intended outcome and its impact on learning. The purpose of the episode was to raise the contextual relevance of the assessment mode by showing that it can be used in a class that is similar to many teachers' classrooms in East Africa. To do this, the episodes indicate the number of students, the teacher's name and the competency being developed. The episode further focuses on the effective use of a particular assessment mode by indicating the teacher's thoughts and reflections when implementing it. The episode then serves as a point of reference for discussions about the assessment mode.

The episode is then followed by three summaries: (1) Key Highlights; (2) Extending the Formative Assessment Process; and (3) Points to Remember. The "Key Highlights" describe the main points a teacher needs to consider to effectively use the assessment practice under discussion. These highlights capture important procedural points from the assessment episode that make it a more effective practice. "Extending the Formative Assessment Process" provides teachers with strategies to further enhance the assessment practice when they are ready to do so. Through our ongoing work with these teachers, we observed they were at different places in terms of their readiness to use these assessment practices. Hence we wanted to provide guidelines that would provide opportunities for teachers to continue their formative assessment "journey." Lastly, "Points to Remember" identifies the major technical aspects of the assessment strategy and breaks down the assessment strategy into various pedagogical activities that ensure the assessment strategy is successfully implemented. The episode finishes with a "Link to the Competency Based Curriculum" to link assessment to learning as provided in the curriculum. This serves to link the assessment strategy to a specific topic and competency while highlighting the benefits of using that assessment (see Appendix 1 for an example).

Discussion

In an ongoing need to improve the learning outcomes of children, education systems in East Africa have adopted a Competency Based Curriculum (MOEVT, 2013, 2015). The current curriculum emphasizes the application of knowledge, skills and abilities to be learned (learning intentions), along with what students need to demonstrate the learning (competencies). As our research

has highlighted, and in alignment with research in other contexts, the barriers to implementation continue to be related to teachers' exposure to current conceptions about teaching, learning and assessment. As agents of educational change, teachers are critical for effective implementation but they require the supports and resources to meet these expectations (Deluca et al., 2012; Wylie and Lyon, 2015), a real challenge in the rural regions of East Africa (Halai et al., 2022; Magidanga, 2021; Ndalichako, 2013). As Halai et al. noted, and as our work also highlighted, these large primary classrooms were characterized by teacher directed feedback that was overly general and focused on the correct answer. These observations were key to our efforts to build teachers' assessment capacities. We realize the explicit work we did with a group of teachers and the Assessment Guidelines we produced will be insufficient to meet this challenge. Nevertheless, our work and research provide examples and evidence of effective implementation, thus providing a pathway for future success.

Overall, it was evident that teachers' knowledge and AfL related practices improved as teachers became more attuned to students' learning gaps and adjusted their teaching appropriately. Consequently, teachers, albeit at a very initial level, were attempting to meet diverse students' needs and attempted to differentiate and adapt their teaching to raise levels of student achievement. While an attempt was made by teachers to better engage students, we did not observe substantial pedagogical changes in this aspect. Throughout the IR process, teachers expressed concerns about student attention amidst concerns a large class would become chaotic, even though participants' IR observations demonstrated that such engagement was very productive rather than chaotic. Unlike questioning, in which teachers were building on already existing practices, self and peer assessment were a complete paradigm shift for both students and teachers from their former assessment practices. For some teachers, this was a jump too far in the 9 months we worked with them.

Not surprisingly, the level of AfL implementation varied amongst teachers. For some teachers, AfL practices were becoming more naturally integrated into instruction (see also Halai et al., 2022). They used feedback from students to adjust their instruction, routinely shared and used learning intentions to assess students learning and used questions effectively. For others, we observed evidence of improved questioning but a lack of continued use of learning intentions and peer and self-assessment. Nevertheless, Our classroom observations and workshops contained numerous examples of shifting assessment practices. In these classrooms, students were becoming more active in class and teachers were using a variety of pedagogical strategies to engage them (Wachira et al., 2017). We also observed teachers as they began to:

- make connections on how assessment supported teaching and learning and they demonstrated an emerging understanding of the different components and practices of AfL.
- provide task-specific feedback rather than grades that helped create a sense of self-efficacy in their students, leading to higher student participation and engagement in class activities.
- use success criteria that shifted the way teachers viewed their role to include the facilitation of learning, and involve students in determining what successful learning looked like.
- Develop skills in the design of different assessment item formats, resulting in improved validity across assessment items
- accept that when teachers share with students what they will be learning (the learning intentions) and what they are looking for in their students' work (success criteria), student engagement and learning improves.

Those of us who are very familiar with the concepts of formative assessment and AfL might conclude that the practices our research highlighted as a result of the instructional rounds, workshops and *Classroom Assessment Guidelines* do not reflect the "leading edge" of work related to formative classroom assessment. Yet for these teachers, the introduction to Bloom's taxonomy and the value of "wait time" represented substantial shifts in teachers' knowledge and classroom assessment practices, further illustrating the importance of the context in which the professional learning is occurring (e.g., Flóres and Sammons, 2013). Perhaps most importantly, our work with teachers has provided further evidence of the need for sustained resources and support if teachers are to develop the capacity to enact the shifts required. While we agree that a focus on assessment techniques is not enough (DeLuca et al., 2015, 2019; Guskey, 2000; Klinger et al., 2016), our research has highlighted that teachers require an entry point in which to build their assessment capacity, and this entry point must build on teachers' current practices and understandings. Those conducting research and working with teachers need to develop a strong understanding of the educational context and work collaboratively with teachers to identify and meet their professional learning needs.

Appendix

The Power of Questions in Assessment

As an early years' teacher teaching children in Class 1 to Class 3, it is very important to continually assess students' understanding and learning during each class. While there are many formal ways to assess students' learning, one of the most important assessment skills a teacher can develop is that of oral questioning. Some teachers believe there is no special skill to asking questions. This is not at all true. The most effective teachers have worked very hard to develop their questioning skills. These teachers know how to ask simple questions to help students begin to think about their learning, and then, using increasingly more difficult questions, these teachers guide students' further thinking and learning. Teachers who understand the Power of Questions, have learned to give students time to think of answers to the question asked. They have developed ways to seek out the responses of many of the students before identifying the correct or desired response. Effective teachers provide opportunities for all of their students to engage in a questioning dialogue, expanding on the answers of their peers, or asking their own questions of the teacher and their peers to further their own learning. Throughout the questioning process, the teacher carefully listens and observes the students in the classroom, using the students' answers to guide subsequent teaching.

The Assessment Guidelines in this Section provide methods to help you develop more effective questioning process to use in your classroom. The use of these guide-lines and your continued practice will enable you to better use questioning methods to support your teaching and to better engage your students. Help your students use fewer assessments and have a better understanding of your students' learning and achievement. It will take practice to develop these skills but your efforts will be rewarded, saving you time and energy while also improving your students' achievement.

The Power of Questioning

A Teacher's Use of Questions

Juma is a Class 1 teacher. She has 135 students in her classroom, many of whom have only started to attend school over the past 2 months. Juma has worked very hard with the class to ensure the children are able to write the numerical versions for numbers between 1 and 1000. The learning intention Juma is trying to meet is "recognition of the concept of numbers" (see Curriculum for Basic Education, Years 1 and 2). Through her years of experience, Juma knows that students often struggle with numbers over 100, often adding 0's into the numbers by mistake.

The previous class, the students began to learn how to write numbers such as 100, 200, 300. Today Juma wants to introduce numbers between 100 and 200. As a review, Juma orally asks all of the students to work in groups at their desk and write down the numbers 20, 35, and 73. Given the size of her class, she asks each table to hold up the numbers when they have finished. Juma does a quick observation of the numbers and notes that each table has the correct numbers.

Juma does a further review at the board, writing the numbers 99, 100, and 200. As per the routine she has created in her classroom, she asks the class to call out in unison each number as she points to it.

To introduce the next part, Juma asks her students to picture in their head, the number 199. She waits five seconds and then asks the students to put up their hands if they think they know the answer.

Juma asks one of the students to come to the board to write out the number 199. Sofya comes to the board and writes the following. And this is where effective formative assessment practices are very important.

Commonly, a teacher would state that the answer was incorrect and would ask another student to come to the board. Such a strategy would not effectively support the learning of the class. Rather, Juma asks students who have the same answer to put their hand up, noticing that approximately 30 students responded this way. She then asks the class to put up their hand if they have a different answer. After 5 seconds, Juma asks Alexander to tell the class how his answer is different than Sofya's answer. Juma then asks Malai if her answer is the same as Alexander's, to which Malai states yes.

The keys to good questioning

The example of Juma highlights several features of effective teacher questioning strategies.

- Juma has the students work in small groups to complete the review and to check their own understanding with each other.
- Juma uses a variety of methods for students to respond to her questions (writing at the desk, oral response, writing at the blackboard).
- Juma gives the students time to think about their answers to her questions (3 -5 seconds depending on the complexity of the question).
- Juma does not immediately tell the students if they are correct or incorrect. Rather she first seeks to determine what her students are thinking.
- Critical to the effectiveness of these teacher questioning strategies, Juma would follow this questioning structure even if the first response was correct.

Extending the Formative Assessment Process

- Rather than having the students raise their hands if they have the same answer, have all the students with the same answer move to one part of the room and students with a different answer go to another part of the room. Ask the students in these groups another question, for example, write down 201.
- Give students a series of numbers to place in order, include the numbers 199 and 1909.

Points to Remember

1. A teacher's questions during learning can provide important information about students' learning, and their levels of understanding and misunderstanding.
2. Always give students sufficient time to think about their answers to the questions you ask.
3. Thoughtful questions can push students' learning beyond recall of information, helping them to explain their own thinking or understanding.
4. Good questions take time to develop and time to ask and answer in class. Take the time and your students will be more successful.

Competency	Topic	Assessment Tool	Benefit
Arithmetic	Identifying numbers	Questioning	Quickly assessing students learning • Increased feedback • Increased student participation • Identify misconceptions quickly • Probing and scaffolding

"Through-year" (or "through-course") assessment systems are proliferating in the United States. What do such systems entail? Assessments in a through-year system are given in multiple, distinct administrations (also referred to as events and components) across a school year and, further, are intended to support (a) creating a summative determination of student proficiency on state content standards and (b) one additional goal. There are at least ten states and associated assessment companies that are in various stages of exploration, design, and development of such systems. Florida is the most recent case, using what its governor calls a "progress monitoring" system.

The current interest in through-year assessment systems appears to be based on strong assumptions about the multiple purposes that such assessments may serve. These assumptions, in turn, lead to claims about the types of inferences and uses the assessment system is intended to support. But strong assumptions require strong evidence. Is there evidence to support the ambitious assumptions associated with through-year assessment? A validity evaluation is an important way to answer this question. This chapter outlines a path for conducting such an evaluation.

Current examples of through-year assessment systems

Many people regard the administration of three or four independent assessments as the typical through-year design, consistent with how districts administer commercial interim assessments. There are many design variations, however, including (a) weekly, standards-aligned assessments based on a diagnostic classification modeling system, (b) delayed-stage adaptive systems, where through-year components serve as "priors" for the end-of-year assessment, and (c) unit-based assessments tied to a common curriculum. And there doubtless will be additional designs by the time this chapter is in print.

Additional goals of through-year assessment

Crafting a successful through-year assessment system design involves the prioritization of goals, acknowledging that not all goals can be met within a single system. The first step in specifying the additional goal(s) is to ascertain the problem users are trying to address that led to their interest in a through-year design.

What's the problem?

In my work, I have found five general problems with the typical end-of-year test that foster interest in the adoption of through-year assessment designs. First, many users, including district and school leaders, teachers, and even parents, have expressed concerns that their current assessments do not produce instructionally useful information. This concern often is directed at the end-of-year state summative assessment, but it also may reflect the lack of useful information from low-quality local assessments. Most assessment experts acknowledge that end-of-year tests are not designed to provide fine-grained instructional information, but that does not prevent users from wanting more.

Second, most school districts already administer interim assessments multiple times a year, with the last interim assessment usually occurring in the spring. This often leads to concerns about double testing: administering an interim and state summative test in closeness, proximity. It is the district leader's choice to double test, of course, but that does not stop them from pushing for the elimination of the state test because they argue they are getting the information they already need.

Third, some state leaders would like to design and implement an end-of-year test that includes rich performance tasks, both to better measure depth of learning and to signal the types of activities teachers should structure in their classrooms. Unfortunately, administering such tasks takes considerable time. State leaders are reluctant to face stakeholder pushback about excessive testing time, and they also are concerned about the associated validity threats due to student fatigue. Thus, they may turn to a through-year design to spread out the end-of-year testing.

Fourth, education leaders and teachers may be concerned that assessing students just once each year inaccurately captures the student's true level of knowledge because of test anxiety, personal factors, and other idiosyncrasies. Therefore, these stakeholders claim that offering students multiple opportunities throughout the school year should provide for more accurate measurement of students' knowledge and skills.

Finally, the cancellation of state testing in spring 2020, because of the COVID-19 pandemic, revealed the single point of failure of state testing. Specifically, stakeholders had put so much emphasis on end-of-year test results that, when the test disappeared, they were left with no data (in their view). Having a set of assessments, aligned with state content standards, administered throughout the year would have avoided this situation.

Additional goals

As stated at the outset, a through-year assessment system must address at least one additional goal beyond the goal of accountability. At least rhetorically, all assessments included in the through-year system are stated to support accountability purposes as well as at least one other use. These goals derive from the problems described above. The following are some common goals associated with the current set of through-year systems.

- State leaders hope to provide instructionally useful information to educators and students throughout the year to enhance the value proposition of state tests beyond accountability. The design could include a flexible schedule for the administration of through-year assessments by districts to better align with the local scope and sequence.
- State leaders hope to reduce the burden of a single-test administration. The end-of-year summative assessment could be spread out so that the end-of-year test administration requires less time. This was the motivation behind the original through-year design of PARCC, one of the US assessment consortia funded through Race to the Top funds in 2010 (although this design was never operationalized because of concerns regarding the impact on curricular sequencing in participating states and the time requirements for multiple administrations).
- State leaders hope to build an assessment system more coherent than the current constellation of an end-of-year state summative assessment paired with a variety of interim assessments. Through-year designs may help states and districts create more balanced systems of assessments than is currently the case.

The additional goals inform the claims the assessment system is designed to support, and these claims inform the validity argument necessary to evaluate the inferences derived from the scores produced by assessment system. For example, if I assert that changing to a through-year assessment system with multiple assessments administered throughout the school year will address needs for providing test score information that can be used to address instructional needs of students, then I am claiming that the scores from through-year assessments yield information at the appropriate grain size and timing to productively support instructional decisions.

Claims and evidence

Gong (2021a, 2021b) outlined some challenges associated with the claims for through-year systems, such as the comparability of (a) our inferences about student achievement from assessments given throughout the school year and (b) those we would make from a single, end-of-year test. I unpack these issues in the sections that follow.

Claims of instructional and accountability utility

Those claiming that components of the through-year assessment system will support improved instruction should specify their claims by drawing on a theory of action or other heuristic. For example, theory of action might specify that teachers should be

able to gain insights at a small enough grain size to target skills and knowledge students had not yet grasped or identify what students need to learn next to maximize their progress. The theory of action is often a first step in validity evaluation.

The through-year assessment system must produce what the U.S. Department of Education refers to as comparable annual determinations (USED, 2016) in order to service accountability purposes. There is no particular time of year at which these determinations are to be made, but they must be comparable across the state's students and schools. In other words, test scores should support inferences regarding what students know and are able to do that is reflective of the student's learning for each school year/grade level or course. Again, a validity evaluation is how measurement professionals examine the warrants for these sorts of claims. I adopt Kane's (2006, 2013) approach to test validity. Thus, before I outline the specific argument, I provide an overview of Kane's argument-based approach to validity evaluations.

Argument-based approach to validity and validation

Kane (2006) proposed two types of arguments: "An interpretive argument specifies the proposed interpretations and uses of test results by laying out the network of inferences and assumptions leading from the observed performances to the conclusions and decisions based on the performances, [whereas] the validity argument provides an evaluation of the interpretive argument" (p. 17). Kane (2013, 2016) later renamed his interpretive argument as the interpretation-and-use argument (IUA). This was more than a simple name change: It signifies the inseparability of interpretations and uses. Kane (2016) summarized this succinctly: "I think of validity as the extent to which the proposed interpretations and uses of test scores are justified" (p. 198).

The interpretation-and-use argument outlines what the user thinks should occur (and why it should occur) as a result of testing and related systemic endeavors, whereas the validity argument involves weighing the available evidence and logic to decide whether the specific interpretations and uses are justified.

The interpretation-and-use argument

The interpretation-and-use argument can be viewed as a mini-theory for understanding the inferences from test scores in the context of a specific use. Like theory, the IUA guides data collection and methods for conducting validity analyses. Validation is not an exercise in confirmation: Just as theories are falsifiable, so too are IUAs. In this light, one can think of the IUA as a series of if-then statements, such as, "If a student scores at the proficient level on the various through-year components, then they have a solid understanding of the required grade-level content and skills." Of course, there are many more if-then statements for any given test and test score across and within the different categories of inference—scoring, generalization, extrapolation, and decision.

An effective challenge to an IUA is to propose and substantiate an alternative hypothesis that is at least equally plausible as the original assertion. Using the present example above, an alternative inference could be as simple as, "If the student scores at the proficient level on the through-year components, but not on the end-of-year test, then the student possesses only partial knowledge of grade-level standards." When an alternate hypothesis is not supported by the evidence, the user can have greater confidence in the original assertion.

Test validation is the process of making assertions about a test, or testing program, and then collecting data and posing logical arguments to challenge those assertions. Using the original assertion and alternative inference in the previous example, the validity evaluator would design studies to determine the degree to which test scores are sensitive to differences in the instructional experience of students who differ in background knowledge and socio-economic status. The evaluator would then analyze these data, considering the original assertion and alternative hypothesis. For example, if the studies indicate that certain student groups, particularly historically marginalized groups, scored well on the through-year assessments, but not on the end-of-year test, in a pattern that differed from students with more privileged backgrounds, we might conclude there are different expectations on the through-year compared to the end-of-year test or these students were not afforded the opportunities to move beyond proximal and fragile understanding of the required knowledge and skills. In short, validity evaluators are continually attempting to challenge the justifiability of a testing program's claims.

Kane (2006) provides examples of four types of inferences—scoring, generalization, extrapolation, and decision—that are useful for structuring an IUA for a testing program. For each intended inference, a set of arguments is established and thoroughly investigated until the claims can withstand counterargument. Kane provides two examples for scoring: "the scoring rule is appropriate," and "the scoring rule is applied accurately and consistently" (p. 24). A person would then identify the most plausible counterclaims/alternative hypotheses, evaluate the most likely of these plausible counterclaims, and, finally, determine whether the arguments for validating the scoring process still hold after investigating different avenues to debunk each stated argument.

Some might question why an evaluator should adopt Kane's framework when we have *The Standards for Educational and Psychological Tests* (AERA et al., 2014) for collecting and organizing validity evidence with respect to test content, response processes, internal structure, relationships with external variables, and the consequences of testing.

To be sure, *The Standards* address critical sources of validity evidence, but they provide little guidance for organizing, implementing, and synthesizing validity evaluations. Therefore, an IUA should be used to frame validity evaluations while integrating the five sources of evidence from *The Standards* as appropriate.

Insofar as through-year assessment systems are intended to have positive instructional consequences, any validity evaluation of a through-year assessment system must search for evidence of both positive and negative consequences. Because such evidence is

a key aspect of decision inferences, naming consequences as a required source of evidence, as is done in *The Standards*, is absolutely necessary.

Applying an argument-based approach to the validation of through-year assessments

In the sections that follow, I describe Kane's four types of inferences (scoring, generalizability, extrapolation, and decision), offer suggestions for evaluating such inferences for through-year designs, and suggest potential sources of evidence where relevant. I limit this discussion to the accountability and instructional uses of through-year systems. I emphasize that the claims and types of evidence I describe in the next section are just examples. Users and evaluators might find these examples useful, depending on the particular context and through-year design, but I have little doubt that the interpretative argument I outline below will need to be tailored to each case.

Scoring inferences

"The validation of a score interpretation involves an investigation of whether the scores mean what they are supposed to mean, and the interpretation is said to be valid if the claims inherent in the interpretation are supported by appropriate evidence" (Kane, 2016, p. 199). Scoring inferences arguably lie at the heart of any validity evaluation, for if the scores do not "mean what they are supposed to mean," then the validity of any subsequent inference—generalizability, extrapolation, decision—is moot.

Scoring considerations for accountability uses of through-year assessments

The US federal assessment and accountability laws require that students are assessed on the full breadth and depth of the state's content standards. This often is demonstrated through alignment studies and cognitive laboratories for end-of-year assessments. In both cases, students are assumed to have had an adequate opportunity to learn the required content standards by the time of testing. Through-year assessments carry the added assumption that the through-year components include items and tasks appropriate to the student's stage of development at the time of testing. This is especially important where students are expected to progress through the year on the domain in question.

The following examples capture how evaluators, examining the plausibility of scoring inferences for accountability uses, likely would collect validity evidence.

- The scoring rules are consistently, equitably, and accurately applied to all examinees. Supporting evidence would come from differential item-function studies and quality-control documentation.
- There are adequate procedures for ensuring consistency and accuracy of scoring for all students and all identifiable student groups. Supporting evidence would be drawn from scoring consistency and accuracy studies as well as reliability/generalizability analyses.
- Where open-ended items are used, the quality of the selection, training, and monitoring of scorers is adequately described. Supporting evidence would come from documentation of training and monitoring protocols, interrater analyses, and generalizability studies.

Scoring considerations for instructional uses of through-year assessments

Scores from a through-year assessment system must provide information for meaningfully shaping instructional decisions. In order to inform teaching and learning, a research-based model of learning must be specified explicitly in the design. A few examples of claims and potential evidence regarding such inferences include:

- Scoring rules for through-year components maximize the utility of the scores for instructional purposes. Supporting evidence could be drawn from studies employing different scoring rules (particularly for subscores) and working with teachers to evaluate which rules yield better instructional insights.
- The use of approved accommodations supports the intended scoring inferences for different types of test items and examinees. Evidence would be derived from studies indicating the relative comparability of accommodated and non-accommodated scores or perhaps differential boost studies that demonstrate the effectiveness of the accommodation for the students who need them relative to students not needing that accommodation.
- The scoring rules for creating a total score from the multiple assessments are defensible and fair; further, these rules accommodate student development through the year, both for all students and for identifiable student groups. Supporting evidence would come from simulation and empirical studies evaluating various approaches against a priori criteria for fairness and defensibility.
- The scoring rules are designed to yield scores, to the extent practicable, that support instructional decision-making by educators and supporting students' insight into their own learning. Evidence supporting this claim could be derived cognitive laboratories using different scoring models to document the instructional insights from the various models.

Generalization inferences

Generalizability theory treats an assessment's items as representing a sample drawn from the universe of all possible items related to the specific learning targets to which the scores are intended to generalize (Brennan, 1992; Cronbach et al., 1972). Generalizability theory addresses the accuracy with which we can generalize from a person's score on a particular set of items to the person's universe score over the population of items, raters, occasions, and other specified facets. Measurement specialists have developed extensive tools and processes to evaluate error (measurement and sampling) and reliability, both of which are subsumed by generalizability theory. Mapping to the *Standards*, generalizability requires a careful specification of the universe of generalization, which can be part of the evidence related to test content, but evidence related to internal structure is also important.

Generalizability considerations for accountability uses of through-year assessments

Through-year assessments must be able to support the same sorts of generalization inferences as end-of-year tests. However, the former have the added burden of considering how occasions (an important facet in generalizability studies, e.g., Shavelson et al., 1993) affect generalizations regarding students' knowledge and skills. While there are many designs that separate the through-year components from the end-of-year proficiency determination, I assume here that the through-year components count in the annual determination. Potential generalizability claims include:

- Scores from the multiple assessment components support generalizability inferences comparable to the end-of-year test in terms of student performance relative to the test blueprint.
- Scores have the appropriate level of generalizability to support accountability-related uses of these scores, for all students and identifiable student groups.
- The combination of the various assessment components support the intended internal structure of the overall test: how items fit together. Supporting evidence would be a confirmatory item-level factor analysis.
- The internal structure based on the combinations of through-year components is similar across identifiable groups (e.g., cultural, racial, language).
- The use of approved accommodations supports the intended generalizability claims.
- The various errors associated with test scores are evaluated appropriately (e.g., through analyses addressing inter-rater consistency or person-by-item interactions) and are found not to hinder generalizability inferences.
- The various sources of error associated with items and tasks are minimized to the extent practicable.

Generalizability considerations for instructional uses of through-year assessments

The most important generalizability considerations for through year assessments when intended to support instructional uses involves the degree to which the items and tasks included on the through-year assessments support instructional decisions concerning the learning targets of interest. Knowing which items a student got right or wrong is less important for supporting instruction than knowing how well a student understands a particular content domain or subdomain. While many of the generalizability inferences noted above also apply to instructional use, the following inferences are specific to instructional uses.

- Scores from each through-year assessment support inferences regarding students' knowledge and skills in specific subdomains, which are meaningful targets of curriculum and instruction. Supporting evidence would include confirmatory factor analyses demonstrating the unique information produced by each subscore (subdomain). Additionally, evidence should be collected demonstrating that these subscores are at a grain size at which teachers can productively act to support student learning.
- The scores from each assessment event have the appropriate level of generalizability to support the intended instructional use for all students and identifiable student groups. Support for this claim includes evidence that the assessments administered throughout the year produce scores that generalize to instructionally relevant aspects of the domain for that time of year.
- Considered together, the scores from all through-year assessments support inferences about students' knowledge and skills relative to the target domain, for all students and for each identifiable student group. Evidence to support this claim could include generalizability studies demonstrating reasonable coefficients as well as studies indicating the scores provide an indication of students' progress through the target domain.

Extrapolation inferences

Many validity evaluations ignore or downplay extrapolation, in part, because it is challenging to gather appropriate evidence (e.g., Haertel, 2018). Generalization is geared to evaluate inferences related to the specified domain (e.g., the eligible knowledge and skills as specified in the test blueprint or related document). Extrapolation evaluates the degree to which inferences about what students know and can do related to the larger domain (e.g., "biology" beyond what is defined by the test blueprint). In some sense, the extrapolation inference is intended to evaluate the degree to which the domain specified by the test represents the larger domain from which the test specifications were drawn.

The relationship of the test scores to other variables, such as test scores thought to measure the same general domain, can help evaluate inferences regarding whether the test scores represent the larger domain beyond the universe of generalization. Supporting evidence includes results from concurrent and predictive validity analyses involving a criterion representing the domain of interest.

For example, college entrance examination providers should provide content-related validity evidence that the test items and blueprints represent knowledge and skills deemed important for postsecondary education. While such content-related evidence is important, the test's predictive relationship with the criterion—postsecondary success as measured by 1st year GPA, for example—is a critical component of the validity argument for using college entrance exams.

Extrapolation considerations for accountability uses of through-year assessments

The extrapolation inference tends to be less important than the scoring, generalizability, and decision inferences when it comes to accountability use cases. Accountability tests must support inferences related to the defined set of knowledge and skills as well as certain transformations of test scores such as for student growth measures (Haertel, 2018). The examples below highlight some types of evidence an evaluator would collect to support inferences related to extrapolation specific to through-year assessments.

- The full set of test scores relates positively to measures of similar constructs (convergent validity) and negatively to measures of dissimilar constructs (discriminant validity). Through-year assessments used for accountability should have evidence as strong as that produced for an end-of-year test measuring the same domain.
- The relationships of test scores and results from other measures are similar across identifiable groups (e.g., cultural, racial, language).
- The knowledge, skills, and other attributes, as measured by the various through-year components are required for success in the target domain, such as in postsecondary education or employment. The judgment of experts, for example, would be helpful in this regard.

Extrapolation considerations for instructional uses of through-year assessments

Extrapolation inferences related to instructional uses address the extent to which students can apply their knowledge and skills to the larger domain—even beyond that defined by the test blueprint. This pertains to the concept of transfer—particularly distal transfer—which is facilitated by deep understanding (NASEM, 2018). Thus, if through-year assessment systems are intended to support instructional uses, system designers must specify the degree to which assessments support deeper learning and transfer. I am not clear if this is a goal of many (all) of the current through-year systems—it does not appear to be the case based on the designs I have seen (e.g., extensive/exclusive use of multiple-choice items), but for those users with a goal of supporting deeper learning, the following are examples of claims related to the extrapolation inference.

- Through-year assessments call for cognitively complex thinking. Supporting evidence could be drawn from alignment studies that include a focus on depth-of-knowledge and cognitive laboratories.
- The assessments' items and tasks are aligned with the target domain, but also are representative of the larger domain. Supporting evidence could come from the judgments of experts.

Decision/use inferences

Kane (2006) supported the investigation of consequences as part of validity evaluation, even though he did not single out consequences as its own category as did *The Standards* (AERA et al., 2014). Nonetheless, he was unequivocal about the relationship between decision inferences and consequences: "A score use involves a sequence of claims that culminates in a decision, and decisions are justified in terms of their expected consequences" (Kane, 2016, p. 198). As such, evidence related to test consequences play a critical role in evaluating the validity of decision/use inferences. Note, because of the connection between decisions and intended uses, I term this inference the decision/use inference following Kane's interpretative and use argument.

Decision considerations for accountability uses of through-year assessments

Through-year assessment systems used in support of accountability decisions must meet rigorous assessment quality criteria, such as validity (except for consequences), inclusion, and reliability. Critically, these systems must support the classification of students into various achievement levels—the resulting proportions being one of the most important accountability indicators. Evaluators examining the plausibility of decision/use inferences for accountability purposes likely would collect evidence along the lines of these examples:

- There is evidence that high-stakes classification decisions, based on the combination of through-year test scores, are supported through multiple types of studies. These studies should address such considerations as decision consistency and accuracy, content alignment, and subsequent performances (e.g., performance in the next grade).
- Classification decisions (e.g., proficient), based on the combination of through-year test scores or based on individual through-year assessments, do not lead to negative unintended consequences, such as restricted (or denied) opportunities and negative labeling.
- Decisions, such as advanced course opportunities, promotion, or graduation, based on the combination of through-year test scores do not carry negative consequences for identifiable student groups.
- The standard-setting process, based on the multiple through-year assessments, results in cutscores that validly and consistently reflect important differences in student performance along the achievement continuum based on documentation of the process

and materials used, surveys of panelists about how they considered the various through-year components, and other relevant factors. Further, there should be evidence that the score aggregation method used results in more defensible cutscores and achievement levels than another potential approach for aggregating through-year scores.

Decision considerations for instructional uses of through-year assessments

Decision inferences to support instructional uses must attend to the types of decisions educators make in response to the test results to guide and enhance student learning. Further, this aspect of the argument must also, based on through-year assessments, must address the potential unintended negative consequences associated with mining instructional information from accountability tests. More specifically, there is the risk that using such tests for accountability purposes corrupts their potential for instructional benefit (e.g., [Campbell, 1979](#)). What follows are examples of the claims and evidence an evaluator would collect to support inferences related to the decision information for instructional uses of through-year assessments.

- Through-year test components yield results at a grain size sufficient to inform instructional decisions. Supporting evidence could come from teacher surveys, classroom observations, and think-aloud protocols with teachers while they review score reports.
- Through-year assessment components measure important subdomains aligned with local curricula. Supporting evidence could be derived from surveying teachers and reviewing local curricula.
- Teachers can interpret and use the results from the through-year components to appropriately adjust instruction for individual students as well for identifiable student groups. Supporting evidence could be derived from classroom observations, video simulations, think-aloud studies, and other means to gather direct observations (rather than simply a survey of teachers' impressions).
- Teachers do not engage in test preparation or other activities that distract from the instructional aims of the assessment system. Supporting evidence could be drawn from interviews with principals and surveys of educators and students.

The validity argument: synthesizing evidence and logic

Cronbach once proclaimed that “construct validation is better seen as an ever-extending inquiry into the processes that produce a high- or low-test score and into the other effects of those processes” ([Cronbach, 1971](#), p. 452)—which may have frightened people from engaging in validation for fear of getting mired in never-ending studies! In fact, the second part of Kane's approach to validation—the validity argument—involves the synthesis of the various evidence collected according to the IUA as well as the theory and logic underlying the assessment system. Unfortunately, this part of the framework has not been described as well as the first, the IUA. Nevertheless, one of the advantages of Kane's approach is that it provides considerably more structure to validity evaluations than the construct model.

Similarly, [Haertel \(1999\)](#) emphasized that individual pieces of evidence do not determine an assessment system's validity. Evidence and logic must be synthesized to evaluate the IUA. Such activities should allow key stakeholders to make overall judgments about the efficacy of the testing program. Yet, there are few examples of validity argument syntheses in either the literature or in practice.

The Standards ([AERA et al., 2014](#)) include a brief note at the end of the validity chapter that provides general guidance about integrating the various sources of validity evidence into a summary judgment:

A test interpretation for a given use rests on evidence for a set of propositions making up the validity argument, and at some point validation evidence allows for a summary judgment of the intended interpretation that is well supported and defensible. At some point the effort to provide sufficient validity evidence to support a given test interpretation for a specific use does end (at least provisionally, pending the emergence of a strong basis for questioning that judgment) (p. 22).

Unfortunately, *The Standards* do not provide guidance for how evaluators should weigh the various sources of evidence when making a judgment about test use. For example, does strong evidence regarding response processes outweigh weak evidence regarding the relationship to other variables, assuming both are relevant to a particular test use?

Kane's argument-based approach appears fairly conjunctive in that the evaluator first weighs evidence related to scoring before moving on to generalization, extrapolation, and ultimately decision/use inferences. This makes sense in many regards. For example, it would be hard to substantiate a generalization claim without confidence in the scoring inference. But it still seems like a high bar for many reasons, including the challenges associated with satisfying extrapolation claims.

The process of synthesizing the empirical evidence and logical arguments into an evaluative judgment can be a challenging activity even when all evidence is available. But in operational assessment programs, new evidence comes in over an extended time frame, especially the consequence evidence, which amplifies this challenge. [Kane \(2006\)](#) anticipated this problem, suggesting that the initial evaluation of an IUA therefore could adopt a confirmationist bias, whereby the developer and key users look for evidence to support the system design and implementation plans in order to get the program off the ground. However, this does not absolve evaluators of planning longer term studies, such as those related to consequences and fairness; but synthesis

and evaluation in the early years of an assessment program should at least confirm that assessment development generally has proceeded as planned, and the design can be supported with early empirical evidence as well as sound logic.

I recognize the notion of synthesizing the various pieces of evidence into an overall judgment is somewhat abstract. Further, as Ryan (2002) pointed out, different stakeholders and users would weigh the evidence differently. An overall judgment might obscure these different needs. Therefore, instead of an overall judgment by a single evaluator, it makes more sense to array the evidence in a profile or similar format. For example, the assessment company, Cognia and MSAA Consortium (2019), has been working with its clients to produce a “validity scorecard,” whereby the various sources of evidence, according to the IUA, are summarized and rated (e.g., strong evidence, weak evidence, no evidence) such that the user is able to determine which components and strength of evidence are most important to them. My only quibble with this particular approach is that there is a conflict of interest with the test company rating the strength of evidence. The evidence could be produced and an independent entity, such as a state’s technical advisory committee (TAC), could offer recommendations regarding the strength of each aspect of evidence. The TAC because of its unique position could also offer recommendations for the state, for example, regarding which categories of evidence should be prioritized.

A call for evidence

I started this essay by pointing out that the current interest in through-year assessment systems appears to be based on the multiple purposes that such assessments are assumed to serve. These assumptions, in turn, lead to claims regarding the types of inferences and uses that the assessment system is intended to support. But strong assumptions require strong evidence. I have not yet seen the evidence, nor the logical arguments, needed to support many of the assumptions associated with through-year designs. Those advocating through-year systems have a responsibility to produce evidence to support their major assumptions and to evaluate this evidence fairly. Perhaps that is because through-year assessment systems are too new to generate the necessary evidence. Nevertheless, there is significant potential for negative consequences as a result of mixing instructional and accountability uses in the same system. Therefore, there is an urgency to begin constructing an interpretative argument and collecting evidence, especially in terms of both positive and negative consequences.

Overview

This section identifies the key themes of this entry, which are elaborated in the sections that follow.

Mathematical literacy (ML) is the ability to use one's mathematical capabilities to better understand the world, its structures and events, and with that understanding to make better-informed decisions. It has become increasingly important as the world changes rapidly; people are faced with more choices, many with uncertain outcomes.

Mathematical literacy is part of literacy in its broader meaning: those aspects of understanding and capability that are of value to most people in enriching their adult lives. These include the ability to understand arguments and to create persuasive ones. What is that politician (or other salesman) saying? What might they actually mean? Given their selection of data, what else might be significant, affecting the outcome? What meaning can I glean from that graph? How can I find good reasons for the action I think desirable, collect information, and build it all into a reasoned persuasive argument? These abilities are important across all school subjects.

The ability to think logically and mathematically about problems as they arise provides key advantages in facing the opportunities and challenges of life and work. The Covid-19 pandemic made this emphatically clear. It led people who are normally busy “just getting on with life” to think about controlling the risks they face, adapting their finances, and wondering about the implications for them of the changing data and model predictions that filled the news.

Learning formal mathematics does not necessarily prepare one for its meaningful use. In a classic study, 70% of the upper elementary students who were asked how many two-foot boards could be cut out of two five-foot board lengths answered “five,” completely ignoring the context in which the problem was set (making a bookcase). The same is the case for what would appear to be directly relevant mathematical tools and techniques learned in secondary school. Although “real world” contexts are increasingly used in presenting tasks, the focus of instruction is usually on the mathematical procedures involved—not the practical implications.

Assessing mathematical literacy. This neglect of mathematical literacy in curricula is mirrored in assessment—with the major exception of PISA, the widely influential OECD *Programme for International Student Assessment*. Since the first tests in 2000, the PISA Mathematics Expert Groups, working with the creative design teams at the Australian Council for Educational Research (ACER) and elsewhere, have developed a sophisticated analysis of the issues involved (see [Stacey and Turner, 2015](#)). The PISA 2021/2022 draft Mathematics Framework, reflecting earlier versions, defines mathematical literacy as

... an individual's capacity to reason mathematically and to formulate, employ, and interpret mathematics to solve problems in a variety of real-world contexts. It includes concepts, procedures, facts and tools to describe, explain and predict phenomena. It assists individuals to know the role that mathematics plays in the world and to make the well-founded judgments and decisions needed by constructive, engaged and reflective 21st century citizens.

Two tasks are shown in Fig. 1. Note that The OECD website for PISA refers to “units” of connected “questions”, also called “items”—the statistical term for a score point that is often used for any task. The tasks in Fig. 1 are items.

Stacey and Turner (2015) review ML and its assessment in depth in the context of PISA. We refer to their analysis throughout, while expanding beyond the tight constraints on assessment allowed by an international comparison study.

The abilities students need to employ, even within one subject like mathematics, are complex. They include not only knowledge and skills, but the ability use them strategically in tackling diverse types of tasks. A valid, full and fair assessment is correspondingly *complex*—as is a valid, full and fair report on the results. This calls for alignment between curricular goals, instruction, and assessment. ML expands the range of learning goals for Mathematics, increasing the dimensions of complexity in designing assessment.

Assessment and accountability: an unhappy marriage. Assessment and accountability arise from very different needs and reflect fundamentally different philosophies although they are often tightly bound in practice. Government at every level needs to document effectiveness at reasonable cost, presenting results in a form that is simple enough for those concerned to understand and interpret. Complexity in thinking and writing as students work through tasks, and in the judgment process, are condensed into simple results, often just one number. Does a score of 70% on an exam, for example, reflect a student's lack of familiarity with some central concepts, or lack of computational facility? Absent more fine-grained feedback, a report of scores may suffice for accountability purposes but may not at all be useful for identifying areas of needed improvement.

The tension between complex curriculum/performance goals and the need for simple summary feedback is resolved in very different ways across different countries, levels of education, and subject disciplines. We explore and evaluate a range of mechanisms for resolving these differences. Our analysis also applies more widely, wherever complex thinking is assessed.

A mathematical literacy curriculum. The strategic purpose of assessment is to improve teaching and learning. The challenge is, what changes are needed to help *all* students develop the mathematical literacy that they need? Necessary changes involve rebalancing the

mathematics curriculum with meaningful real world tasks and modifying instruction in ways that give students more responsibility and agency in their learning (see Schoenfeld and The Teaching for Robust Understanding Project, 2016 and Teaching for Robust Understanding, 2015, TRUframework.org). Numerous small-scale curriculum projects (typically at the school district level, affecting at most a few thousand students), demonstrate that these issues can be dealt with productively. However, there is still much to learn about the design factors that enable such projects to succeed, and how to implement such projects at scale. Assessment will play a central role in any transition because of the way it both reflects and influences the curriculum. Mathematical Literacy is in most governments' stated goals but it is rarely supported in practice (e.g., in curricula or assessment). There remain unsolved issues of systemic change (Burkhardt, 2019).

What you test is what you get (WYTIWYG). Assessment providers traditionally claim that examinations merely sample performance; "Of course, all good teachers teach much more than that." However, in systems where schools and teachers are judged on student test scores, most teachers focus their teaching on tasks similar to task in the tests on which their students will be judged. This effect has gradually become recognized, as is the need for broader, more balanced assessments. However, any comparison of the official learning goals with the types of performance actually assessed in most official examinations shows that a profound difference remains. Since most teachers will, understandably, teach to the test, developing "tests worth teaching to" is a key responsibility of those in authority.

Teaching for Robust Understanding (TRU). High quality instruction—instruction from which students emerge as knowledgeable and resourceful thinkers and problem solvers—has been shown to depend on the degree to which the following five dimensions are present: (1) rich disciplinary content and practices; (2) opportunities for "productive struggle" and sensemaking; (3) equitable opportunities for *all* students to engage with core disciplinary ideas; (4) opportunities to contribute to classroom activities in ways that contribute to the development of a sense of agency and positive disciplinary identity; and (5) the use of formative assessment in the service of dimensions 1–4 (Schoenfeld, 2020; see also <https://truframework.org/>).

The sections that follow explore these issues. The section **Mathematical literacy—what is it and why is it important?** sets out the essentials of mathematical literacy, with illustrative examples. The section **Assessment tools and processes** addresses key factors in assessment. The section **A spectrum of assessment models** describes four very different models of assessment in wide use, and their strengths and limitations for assessing ML. The final discussion considers ways in which assessment of ML could change for the better.

Mathematical literacy—what is it and why is it important?

This section provides tasks that exemplify mathematical literacy and assessments that capture it.

The defining role of tasks

Currently the teaching and learning of mathematics is focused on the acquisition of procedural fluency—arithmetic in the early grades, symbolic (primarily algebraic) in later grades. The assessment tasks in Fig. 2 are typical both in their nature and brevity. It is assumed that students should *remember* how to do the task from practicing closely similar tasks in class.

In contrast, the task-types at the heart of mathematical literacy involve much more substantial reasoning. Typically, such tasks ask students to:

- Interpret and translate—*Extract meaning from data, move between representations*
- Explore and discover—*Find relationships, make predictions*
- Evaluate and improve—*Review and improve an argument, a plan, or an artifact.*
- Model and explain—*Invent, interpret, and explain models of real world phenomena*

or, more proactively, to

- Plan and organize—*Find an optimum solution subject to constraints*
- Design and make—*Design an artifact or procedure, and test it.*

Arithmetic	Algebra
• $735 - 546 = \frac{[1]}{[SEP]}$ • Find the sum of the integers from 11 to 19 • In a grocery store, 4 Kg of tomatoes cost \$5. How much will 7 Kg cost?	• Solve $3x + 5 = 21 - 5x$ $\frac{[1]}{[SEP]}$ • Factor $x^2 + 3x - 4$ $\frac{[1]}{[SEP]}$ • Write $\sin(A + B)$ in terms of $\sin$ and $\cos$ of A and B. $\frac{[1]}{[SEP]}$

Fig. 2 Some typical tasks from school mathematics.

Fig. 3 illustrates four of these task-types. While students are expected to have encountered tasks of these general types in instruction, and to be familiar with the real world contexts from which the tasks are drawn, the specific situations to be analyzed are meant to be new. The mathematical techniques needed for these tasks are standard, but each task also requires strategic thinking including thinking through appropriate representations, which aspects of the context need to be captured, which approaches might be profitable, and how to judge the reasonableness of the answers that emerge.

In examinations successful students would typically take 10–15 min to work tasks like each of these. If there is more time available in the curriculum or in assessment, each problem can be expanded in ways that reward deeper exploration.

There is the question of how “real” a task needs to be in order to reflect ML. Burkhardt (1981) classified tasks as: Action, Believable, Curious and Dubious (just to practice the mathematics, as in Fig. 2). PISA 2012 describes problem contexts as *personal*, *societal*, *occupational* or *scientific*, using the classification in balancing the variety of tasks chosen for the survey sample (Stacey and Turner, 2015).

Task difficulty increases with *technical demand*, *complexity*, *unfamiliarity*, and *the length of the chain of reasoning* that the student needs to construct. In traditional mathematics tasks such as those in Fig. 2, difficulty is modified by adjusting technical demand. In contrast, the challenges of mathematical literacy tend to lie in the other three, less technical dimensions. For assessment purposes, where comparable overall difficulty across a range of tasks is called for, technical demand must be lowered to allow for challenges of interpretation, representation, and reasoning. Indeed, Steen (2002) described mathematical literacy as the sophisticated use of relatively simple mathematics, contrasting it with the reverse priorities found in school mathematics. Task difficulty is notoriously easy to misjudge. Stacey and Turner (2015) describe how the creative team for PISA 2012 first estimated the likely difficulty of each task. They then established the difficulty by trialing the task with a cohort of appropriately prepared students in each country, analyzing the responses. This is the only reliable way to establish the difficulty of a complex task.

Fig. 3 Mathematics in the real world. Tasks reproduced, with permission, from the Mathematics Assessment Project (2015).

Implications for teaching and learning

The tasks in Fig. 2 reflect a common teaching style, based on “demonstrate and practice” of skills. However, practice alone sustains skills; long-term maintenance depends on having an understanding of the underlying mathematical concepts (see, e.g., Black and Wiliam, 1998).

Due to the fact that most instruction aims at the kind of narrowly focused content-based learning exemplified in Fig. 2, the strategies and extended reasoning one needs to use mathematics in a literate way do not figure much in current school mathematics—or in the understandings of the adults that emerge. Very few classrooms focus on real world problems as substantial as those in Fig. 3, let alone more extended investigations of issues and data of concern.

Typically the purpose of “real world” problems is to provide concrete examples of a concept or skill—perhaps through the counting of stones, or their pairing to illustrate odd and even numbers. A more advanced example is the exemplification of exponential growth by the famous “rice grains on a chessboard” puzzle: “If the number of grains doubles from square to square: 1, 2, 4, 8, ... until all 64 squares are covered, how many grains are there in total?” The initially surprising answer is $2^{64} - 1$, with half of the grains on the 64th square. In fact, this number is around 20,000,000,000,000,000,000. The size of this number vividly makes the point that the phrase “growing exponentially” means much more than its common (mis)use to mean “growing very fast.” Equally clear is that the “chessboard” in the problem statement is conceptual and not possibly real; clearly that many grains of rice don’t fit! “Transfer” to the real world is dubious, as evidenced by the difficulty people had in understanding the truly exponential growth of Covid-19. In reality, when the “doubling time” is a few days, a week or two’s delay in making a decision can make an epidemic a massively different challenge for the health system.

Addressing ML seriously calls for significant changes in instruction:

- Longer timescales—Getting to understand any significant real world situation takes time. Even the classroom problems in Fig. 3 require 10–15 min of thought. Many richer problems are more suited to extended project work. This is common in other subjects but rare in mathematics.
- Reasoning, not just answers—The analytical thinking that is at the core of ML involves building extended chains of reasoning, setting out assumptions and developing them through to a set of conclusions. Such chains of reasoning are essential.

For example, in the Airplane Turnround task in Fig. 3, “the answer” (65 min) depends on the assumptions as to which of the processes listed are necessarily sequential (e.g., unloading before loading; but can you refuel while there are still passengers on board?).

- Communication—Explaining your chain of reasoning in a form that others can understand is an essential part of mathematical literacy—and literacy more widely.

It is clear that all these elements are aspects of a strong response to the assessment tasks in Fig. 3. The modeling and data analysis processes involved in understanding a situation of interest like this, asking and answering questions about it, are summarized in the PISA elaboration of the now-standard modeling diagram, Fig. 4.

Fig. 4 The PISA 2012 model of mathematical literacy.

The skill set implicated in Fig. 4 is quite complex but, with appropriate teaching, has proved to be accessible to all students. For students to employ the skills in Fig. 4, the mathematical techniques needed must well-integrated into their network of understanding. Developing increasing sophistication involves working through a wide variety of tasks and task types, along with some explicit teaching of problem solving strategies and tactics.

The essentials of classrooms that produce mathematically literate thinkers are summarized in the five dimensions of the TRU framework (Schoenfeld and The Teaching for Robust Understanding Project, 2016; TRUframework.org). Teaching for Robust Understanding requires: (1) high quality content; (2) appropriate cognitive demand, engaging students in productive struggle; (3) equity, ensuring that all students are productively engaged; (4) opportunities for agency and identity, so that students feel the reasoning is their own; (5) formative feedback, from fellow students and the teacher. This takes many teachers of mathematics beyond their current practice and experience. For a discussion see Burkhardt and Schoenfeld (2019).

Assessment tools and processes

The range of task types in a *balanced assessment* should mirror those used in learning activities in classrooms, and be aligned with the performance goals of the curriculum. Such alignment is rarely realized in practice for reasons that are explored here.

Assessment designs intended to provide useful feedback at the individual student or school or district level normally specify the following elements:

- a desired range of knowledge and performance
- a set of task types sampling this range
- the circumstances in which the students will work on the tasks
- a scoring process, using rubrics for each task in evaluating student responses
- an aggregation process for assembling the scoring information into reports
- a way of communicating the results to users.

To explore how these are realized in practice we first examine properties of assessment systems, and then compare specific modes of assessment that exemplify different approaches and priorities.

Desirable properties of an assessment system

What features do reasonable people expect from an official assessment of their children? Using non-technical language the desirable properties of assessment include:

Fairness—widely agreed to be essential. Two similar performances under similar circumstances should be judged as comparable, independent of the individuals involved in the assessment. Fairness demands *equity*: that the assessment should not be in a form that favors one social group over another. Fig. 5 illustrates a quote from Albert Einstein: “Everybody is a genius. But if you judge a fish by its ability to climb a tree, it will live its whole life believing it is stupid.”

Fig. 5 One illustration of equity as an issue.

Validity of coverage and balance—what is actually assessed. Assessment should match what students have been taught; this, in turn, should fully address the learning and performance goals of the curriculum. In track and field athletics the 10 events in the decathlon are seen as a valid measure of overall “all around” ability. Any one component, such as the 100 m race, is not—it is a valid assessment only of speed over 100 m. Similarly, a spelling test is not a valid assessment of English proficiency, and a set of arithmetic exercises is not a valid assessment of mathematics literacy.

Assessment that has a narrow range, e.g., assessment focused primarily on learned procedures in mathematics, cannot validly assess mathematical literacy when curricular goals include substantial chains of reasoning, communication, and problem solving (Similarly in English, tests of spelling and grammar cannot be said to address issues of literacy).

Interpretability of test scores. What judgments can reasonably be inferred from the scores? Are differences in scores meaningful enough to justify the consequences for students and for teachers and schools that result? This is often called *consequential validity*.

Objectivity of scoring. Are all responses scored on the same basis, avoiding subjective judgments that may vary? This is a key aspect of fairness.

Reproducibility of results (often misleadingly called *Reliability*). If a student takes a different but supposedly equivalent assessment with a different scorer, what is the likely difference in the scores? What are the inter-scorer and test-retest contributions to this variation?

Cost. How much money, and time that may otherwise be used for teaching and learning, does the assessment require?

The ordering above puts educational priorities first. Where accountability is the priority, the order is different, possibly even the reverse. The science of *psychometrics* handles these issues in sophisticated statistical ways that we will not address, other than to note that in nations that employ high-stakes assessments, a key factor in assessment design is the legal defensibility of scoring systems, which is typically insured by task simplicity. Tendencies in that direction are in tension with the desired complexity of meaningful assessments of mathematical literacy.

The importance of the tasks

The tasks and rubrics used in an assessment provide an upper bar on its validity: no meaningful statement regarding any aspect of domain performance is possible if tasks from that domain are not included in the examination. For example, tests that exclude meaningful opportunities to engage in extended chains of reasoning or in problem solving cannot plausibly claim to assess mathematical thinking. As the examples that follow show, many assessments fail this test.

The mismatch between ostensible coverage and exam content is more egregious in Mathematics than, say in English, where examination tasks and their rubrics often cover a broad spectrum of performance that ranges from technical aspects like spelling and grammar to extended pieces of writing varying from commentary and argument to poems and drama. In Mathematics examinations, tasks that require the student to construct extended chains of reasoning on the timescale of an essay are rare at school level; most exam tasks take only a minute or two, assessing recall of learned procedures. Even “problem solving” tasks rarely take more than a few minutes.

The assessment process

Converting a set of tasks that cover specific learning and performance goals into a meaningful and useable assessment involves taking into account the elements noted above: circumstances of performance, scoring, and aggregating scores into a report for users of the results.

Circumstances of performance. Validity depends on students working on the assessment in a mode that enables them to show what they know, understand and can do—not, for example, having to respond on a computer when they are used to working on paper, or vice versa. A fair and valid assessment gives students enough time to show what they can do; if not, students are being assessed on their speed or ability to work under pressure, not on what they know and can do.

Scoring. The evaluation of each student’s response to a task is typically guided by a more-or-less detailed “scoring rubric”, which specifies how to distribute credit across the elements of performance. The design of the scoring rubric is thus integral to the design of the task. It implies value judgments on which people may and do differ. In mathematics, for example, how far the real world context of the task is taken seriously? This is absolutely central for assessing mathematical literacy but still rare in Mathematics assessments. Machine scoring may be reliable for short items, but there are costs in task complexity.

Aggregation and reporting. Different users of the results of an assessment have very different needs and priorities. Teachers can profit from access to the rich information contained in each student’s work—full scripts reveal the student’s thinking. For teachers there is no substitute for seeing the actual scored responses. Although this happens naturally in classroom assessment, it is unfortunately rare in external assessment for practical reasons including cost—and to avoid disputation over scores. The simple results on external accountability measures provide no useful formative guidance for improvement. Computer technology offers the opportunity for sophisticated ways of integrating the data from a student’s responses, allowing profile scores with several dimensions, but this use of technology is rare.

WYTIWYG: what you test is what you get

In practice, where assessment has significant consequences for teachers and students, it is not surprising that teachers in most classrooms focus on the types of tasks that are in the mandated assessments. With high-stakes assessment, what you test is what you get; the tested curriculum *becomes* the implemented curriculum. As a result, the true validity of testing depends on how close the tested curriculum is to the intended curriculum.

The illusion of accuracy

People have come to view examination results as a true and just measure of a student's ability in the subject of the test. If this were true, a response scored by a different scorer would get the same score; but this *inter-scorer consistency* is far from perfect—particularly for extended response tasks such as essays but not only for these. Then there is *test-retest variation*—if the same student tackled a supposedly equivalent examination, would they get the same score or grade? The answer is “sometimes”. For example, in the important school leaving “A-level” examination in England, experts recognize that about half the students would get a higher or lower grade (on the scale A-F) on an equivalent examination—the previous year's, for example. This change could affect whether students get into the university of their choice. Even more serious are tests where the outcome is more life-changing—for example, the “11+” test that determines whether students go to a more, or a less academic high school. One study had the same students take tests from two different years; only half the students that “passed” in the two tests were the same. Even in multiple choice tests that are designed to optimize consistency, random variability of about a quarter of the points assigned is normal.

In summary, high-stakes examinations have not only limited scope but, more importantly, limited accuracy—and thus an element of lottery. We do *not* advocate efforts to improve accuracy, because this is often done at the expense of validity, often by narrowing the task set to exclude richer tasks that involve extended reasoning. Quite the reverse. We believe that society would benefit from openly recognizing the random element in examination scores, then lowering the stakes by giving weight to other information, such as the student's record in their school. This shift in emphasis would open up the possibility using more open tasks that better reflect mathematical literacy.

We note that in the UK, studies show that students from disadvantaged backgrounds do better at university than more advantaged students with the same examination grades. Studies in the US have shown that school grade point average (GPA) is a better predictor of undergraduate performance than the psychometrics-driven school aptitude test (SAT). For this reason among others (e.g., serious concerns about equity), the University of California and other prestigious institutions in the US no longer consider SAT or ACT test scores as a factor in admissions or fellowship decisions. Rich data can give a more useful picture than that from narrower formal tests.

A spectrum of assessment models

There is a wide variety of ways that assessment is realized in practice. The four examples below span the range of styles. The sequence in 4A to 4D may be characterized as a ladder of decreasing richness of information and complexity. These reflect the different needs of their primary users. We shall look at each of these approaches from various perspectives, noting the different balance among the desirable properties we described above.

Assessment as part of instruction

This takes various forms including regularly scheduled tests and, less formally, teacher observations of student work while teaching. Fig. 6 presents an ML task from a professional development module from bowlandmaths.org.uk—“believable” in a societal context. The module focus is on *Handling unstructured problems* in the classroom, where the teachers compare this task with a “school math” version that guides the student through the process step by step.

The primary purpose of classroom assessment is, or should be, *formative*—to guide the teacher's subsequent instruction to better fit the needs of each student. Realizing formative assessment in their classroom is challenging for teachers: while all teachers diagnose student difficulties at some level, making effective modifications to one's next move with a class of 25 individual students is not easy. Doing so requires adaptive expertise (Hatano and Inagaki, 1986) and a supportive curriculum that utilizes student-student discussion, both to reveal misconceptions and to help students resolve them. Black and Wiliam (1998) showed that formative assessment can substantially improve student learning. Burkhardt and Schoenfeld (2019) documented the support that specifically designed teaching materials, exemplified by the Formative Assessment Lessons at map.mathshell.org, can provide teachers in meeting the challenges.

Many of these lessons focus on mathematical literacy. For example, *Matchsticks* asks students to estimate how many matchsticks could be made from a pine tree, given the dimensions of both. The lesson structure provides feedback for the teacher and for peer assessment by students on: the students' assumptions; their concepts of length-area-volume; changes of units; and the proportional reasoning that is involved at multiple points in the problem. *Medical testing* addresses some counter-intuitive but essential understandings regarding proportions of false positives.

Organising a table tennis tournament

You have the job of organising a table tennis league.

- 7 players will take part
- All matches are singles.
- Every player has to play each of the other players once.
- There are four tables at the club.
- Games will take up to half an hour.
- The first match will start at 1:00 PM.

Plan how to organize the games, so that the tournament will take the shortest time.
Put all the information on a poster so that the players can easily understand what to do.

Fig. 6 A planning and organizing task.

Summative assessment is a standard part of teaching practice, with class tests using tasks of the same type as in the curriculum. The tasks in [Fig. 3](#) were designed for assessing ML in this way. Test scores often become part of a student's record. How this record is used depends on the school and the system. In the US, the continuing Grade Point Average is important in guiding decisions about a student's future, within and beyond the school. In the UK it plays a less important role, mainly guiding within-school decisions about future curriculum options.

Analysis. It is straightforward to design classroom assessments of mathematical literacy with high validity—provided that ML is part of the curriculum. The rich tasks and chains of reasoning that ML involves are suitable for both the normal pattern of lessons and for assessing student performance. Test results are directly interpretable in terms of the task types included; interpretation in terms of modeling skills and conceptual understanding may require the deeper probing that is characteristic of formative assessment. Objectivity is limited, particularly when teachers work alone. The same applies to reproducibility. There is no additional cost to this kind of assessment. Teacher time spent evaluating student work may provide diagnostic information that informs better-focused instruction or summative testing for accountability through the student record.

Coursework

Sometimes called *portfolio assessment*, coursework assessment involves selecting and evaluating of pieces of work produced by each student during the school term. If a portfolio includes substantial pieces of work on rich problems from real world contexts, this approach fits the assessment of mathematical literacy well.

To address the possibilities of limited objectivity and reproducibility, portfolio assessment imposes constraints that improve consistency. Detailed guidance may be given regarding the range and balance of task types to be included, and detailed guidance on the scoring. In some cases actual tasks are specified although it is common to offer a choice of tasks, particularly for the extended pieces of work. In some cases, as in the practical assessment of Fine Art, the task-set is left entirely to each student and their teacher. Scoring such tasks employs generic quality criteria.

Given the extended timescale and the resources available from the classroom and beyond, a wide variety of tasks can be included. Two ML examples illustrate this. A UK examination for age 16 included among the coursework options the task *Design a Leisure Center*, the response being an entry for the town's design competition in the form of a scale plan of the site and buildings, with explanations of the design choices made. The extended problems in the school leaving examination for the Victorian Certificate of Education (VCE) were more closely specified, as with *Oil Pipelines* in [Fig. 7](#) (There is more about this VCE examination, which achieved remarkably high validity through the variety of task types included, in the section [A spectrum of assessment models](#) in [Burkhardt, 2009](#)).

There is similar diversity in approaches to scoring coursework and in how such scoring is monitored. Scoring rubrics can be task specific and detailed, or more generic. The open task *Design a Leisure Center* asks for wide ranging thinking and for data collection regarding plausible assumptions, such as the size of areas needed for different recreation activities and how they may fit together efficiently and pleasingly. The design of scoring rubrics that are objective and reproducible for such tasks is less straightforward than for well-specified tasks like "Oil Pipelines"—but consistency can be at least comparable to that in scoring English essays. Student choice among a group of tasks offered also presents comparability challenges. Such challenges can be tackled by trialing the tasks and adjusting the rubrics. Generic rubrics that give credit for higher-level aspects of the response are sometimes used for coursework.

When high stakes are involved monitoring systems are typically employed to improve consistency of scoring. Sophisticated systems involve groups of teacher-scorers comparing samples of scored student work—first within a school and then across a groups of schools, with a chair from the exam board. This activity is also a mechanism for powerful professional development, spreading

Fig. 7 A VCE problem solving investigation (modified).

good practice through discussions of examples of student work. In a simpler model, teachers score work from other classes than their own, then a lead scorer monitors samples of each scorer's work. In both cases scores for a whole group are adjusted on the basis of the sample.

Analysis The central characteristics of coursework are task timescale and circumstances of performance—not only can extended pieces of work, including projects, be included in the package assessed but students have time to check and refine their responses. This is much closer to the way adults are assessed in their life and work. Provided there is some control over the range of tasks, validity can be exceptionally high. The body of information contained in the responses of each student provides a rich, multidimensional picture of the student's capabilities, in contrast to the single number that results when student performance is boiled down to one numerical indicator for accountability purposes. Objectivity with a strong monitoring system is high, as is reproducibility because of the large body of evidence included. The cost of this approach is high both in the teacher time needed for careful scoring and in the monitoring process. However, any cost-benefit analysis should take other aspects into account: careful attention to and feedback on student work can yield significant student learning gains.

British work from the 1960s and 70s on has shown that carefully designed assessment based entirely on coursework could combine their intrinsic validity with a level of consistency comparable to timed examinations, when there is a process of consensus monitoring of teachers' scoring overseen by an exam board (Gibbons and Marshall, 2010). Some US states also developed comparable systems of "collaborative standardized assessment". However, trust in coursework remains a significant political problem. Policy makers have used the specter of cheating as a reason for reducing the role of coursework or eliminating it altogether from many high-stakes assessments. This was the fate of the expert group's recommendation for carefully structured and monitored coursework for the assessment of the National Curriculum in England—the politicians chose tests.

Timed examinations

Examinations are the typical mode of assessment in many countries, with tasks varying from short correct/incorrect items to open or "essay" questions involving more extended chains of reasoning. A few-hour timescale allows a wide variety of task types to be included, each taking the successful student anywhere from a few minutes to an hour. This approach can cover most of the kinds of performance implied by the learning goals in most subjects, including mathematical literacy. Students responses are scored centrally by teachers or others with subject expertise following a more-or-less detailed rubric that distributes credit among different aspects of a successful response. The rubric is normally specific to each task. Mathematical literacy tasks like those in Fig. 3 fit well into such examinations.

Opportunities for high-validity timed examinations are rarely realized in practice, particularly in Mathematics where expected task time tends to be much shorter than for other subjects. There have been enough successful examples of Mathematics examinations including rich tasks that require 10–20 min of solution time (see Burkhardt, 2009) to suggest that their typical absence is a systemic issue: changing high-stakes examinations causes controversy, which politicians tend to avoid. Equally, tasks that require

extended reasoning necessitate the kinds of changes in the ways that mathematics is taught and learned that were described in the section **Mathematical literacy—what is it and why is it important?**. Thus what one sees in mathematics assessments of this type is a trade-off between complexity (of tasks, supportive pedagogy, assessment mechanisms, and interpretation thereof) and tests that are easy to score and reliable—even if the reliability comes at the cost of representing true proficiency.

The variation of scores between different scorers is likely to be much greater for extended chains of reasoning, as in ML or in English, than in Mathematics. In Mathematics high inter-scorer consistency, often a source of pride, is largely the result of limiting the task types to short items with correct/incorrect answers. It is notable that the wide disparities between subjects, in both validity and accuracy, is socially accepted as part of the general practice of assessment, even though a difference of one grade in a school leaving examination can have life-affecting consequences. Hence tasks that assess mathematical literacy should not be excluded on those grounds. The task in Fig. 8 and its associated rubric provide an example of how complex reasoning can be assessed in a reasonably consistent way.

The original “Mathematics version” of this task called for identifying the student with the best average score, rendering the context just a pretext for computation. The version in Fig. 8 is much more realistic. It calls for an understanding of the context and the use of more sophisticated mathematical reasoning regarding what each measure does and doesn’t tell you.

Analysis. Specific rubrics of this kind tend to have high objectivity and reproducibility. Regarding validity, the limited time of an examination and the need to assess a reasonable sample of the curriculum limits task length compared with coursework—but a range of task types listed in the section **Mathematical literacy—what is it and why is it important?** can still be sampled. Such assessment for ML is much broader than in Mathematics, where actual examinations rarely cover even their own stated performance goals. Interpretability is limited by the common practice of reporting just a single score; “profile reporting” with several scores (e.g., for skills, reasoning, problem solving) is an improvement, but remains rare. The cost of the examination is relatively low, as is the class time required—a few hours per subject. Provided that the balance of task types reflects the learning goals for the course in a balanced way, time spent preparing for the examination is valuable learning time.

Short item multiple choice tests

This kind of test of Mathematics has long been favored in the United States for large-scale implementation, e.g., for many state-wide assessments and for pre-college “achievement” tests. Machine-scoring means the objectivity is high. Professional input comes in the design and development of the test, which is often a complex and expensive procedure ruled by psychometric considerations. The direct cost per student is low and little classroom time is needed to administer the test. However, the real cost of such exams can be

Long Jump

Our school needs to select a girl for the long jump at the regional championship.

At the school jump-off three girls have 6 jumps each. Their results, in meters, are given in the table.

Elsa	Ilse	Olga
3.25	3.55	3.67
3.84	3.99	3.78
4.1	3.61	3.92
2.95	3.97	3.62
3.66	3.69	3.85
3.86	3.59	3.73

Hans says:
“Olga has the longest average. She should go.”

Do you think Hans is right? Explain your reasoning.

Suggested rubric
7 minute task >> total 7 points,
partitioned to reflect importance

Points	Criteria
1	Recognize that this is about choice of criteria for likely success in long jump.
1+1 each up to max of 4 points	List criteria (other than average) + some explanation, e.g. • Longest jump; ultimate criterion • Average of two longest jumps; gives some weight to consistency • Average of longest four jumps; allows slips such as “no jumps”.
2	Correctly compute numbers required (-1 for each error)
7	Total

Fig. 8 Long jump—a mathematical literacy task with scoring rubric.

high because teachers typically spend several weeks of class time on otherwise unproductive test preparation. Validity is an issue because the design is constrained by the format: tasks must be short, usually taking a successful student less than a minute—which is very different from the extended chains of reasoning that Mathematical Literacy (or indeed, any substantial problem solving) typically involves.

Despite this PISA, the outstanding assessment of ML and arguably the most influential test in mathematics worldwide, largely in this format. The choice of format was driven by the constraints on any international comparison assessment—notably:

- the tasks must present an equivalent level of challenge when translated into many languages and cultures;
- consistency of scoring is essential if the politically important comparisons for which PISA is used are to be trusted. It is only possible to achieve this across multiple cultures through the use of very simple rubrics.

The quality of the PISA tests is widely respected. That raises questions of how this has been achieved and what the limitations of this model for assessing ML might be.

The design and development of these tests (see [Stacey and Turner, 2015](#)) involved combining principles developed by the PISA Mathematics Expert Group with creativity in task design and academic rigor from the item writing teams at the Australian Council for Educational Research (ACER) and in the contributing organizations around the world. These groups developed coherent units that involved a sequence of questions/items of increasing difficulty, each item with a short response. A rich collection of these units can be found as “released items” on the OECD PISA website. These include the tasks in [Figs. 9 and 10](#), which address the two key elements of mathematical literacy—using data and modeling.

Which Car? involves reasoning to find meaning in quantitative data—in this case using the three criteria in sequence to eliminate alternative cars. *Revolving Door* is a very challenging modeling task: How big can the openings be such that air can never flow freely between the entrance and the exit.

PISA contributes significantly to the assessment of ML worldwide, not least because its name, *PISA Mathematics*, opens the door to such tasks being used in regular mathematics courses and assessments. However, the limitations of PISA’s assessment format are clear. Tasks are longer than is typical in multiple-choice mathematics tests but still short. They require somewhat longer chains of reasoning but still exclude the coherent explanations of extended reasoning, characteristic of ML that other assessment modes allow. Longer tasks within the test time mean a smaller sample of each student’s performance range but coverage is achieved in the national samples by spreading a large number of tasks across different students.

WHICH CAR?

Chris has just received her car driving license and wants to buy her first car.

This table below shows the details of four cars she finds at a local car dealer.

Model:	Alpha	Bolte	Castel	Dezal
Year	2003	2000	2001	1999
Advertised price (zeds)	4800	4450	4250	3990
Distance travelled (kilometres)	105 000	115 000	128 000	109 000
Engine capacity (litres)	1.79	1.796	1.82	1.783

Chris wants a car that meets **all** of these conditions:

- The distance travelled is **not** higher than 120 000 kilometers. [1] [SEP]
- It was made in the year 2000 or a later year. [1] [SEP]
- The advertised price is **not** higher than 4500 zeds.

Q1: Which car meets Chris’s conditions? [1] [SEP]

Fig. 9 Data analysis—a PISA task.

Fig. 10 Modeling with mathematics—based on a PISA task.

Given the international nature of PISA there are cultural limits on tasks that require students to bring in information that is not explicitly provided, an essential part of ML. Nonetheless, increased use of such tasks would be beneficial. That they remain rare is, in view of PISA's political significance in many countries, further evidence of the system-level difficulties of changing established high-stakes assessments.

Analysis. A student's responses to well-designed multiple-choice items, with distractors reflecting common misconceptions, can form valuable diagnostic information for teachers on conceptual understanding, but only when viewed at the item level. As assessment of a complex subject like ML (or Mathematics or English) multiple choice tests alone have low validity. These are not the performances that teachers should focus on developing in their students; the psychometric justifications for validity depend on correlations to meaningful tasks, not the tasks themselves. Objectivity is indeed high, reproducibility is moderate—and machine scoring can keep the cost low if class time spent on "test prep" is excluded. Interpretability is usually limited by the small range of task types that are included, as well as by single number reporting. PISA, however, has shown how far these limitations can be minimized.

Finally, the skill of the PISA design team and the costs of task development should not be underestimated. Finding the talent and the funding to modify PISA for purposes other than large-scale assessment would be a challenge.

Routes to better assessment

Policy makers need assessments that provide them with data to monitor the education systems for which they are responsible. We have shown that there is a great variety of ways this is done, each having a different balance of desirable features. But an assessment cannot be more reliable than it is valid; in any normal understanding of those terms, you have to assess what you want teachers to teach and students to learn. Those who choose accountability that relies primarily on multiple-choice tests are thus accountable for the damage done to the teaching and learning in their systems. In contrast, there do exist systems that provide the necessary feedback for accountability at reasonable cost and provide pressure to enhance the quality of teaching and learning. This implies giving priority to validity.

We have set out the many reasons why an accountability system that strategically aims to improve learning should be based on the use of assessment tasks that together represent a broad and balanced sample of the knowledge and performances that represent high-quality learning in each subject. We have pointed to examples of large-scale implementation of assessment systems that have met these standards. The central issue in the design of such a system is the balance between validity and objectivity, so different across the models in 4A to 4D above, taking into account the likely effect on what is taught. A combination of coursework and timed examinations ranks high on both these desirables.

The best overall approach to meeting the multiple goals of assessment for any domain as complex as Mathematical Literacy is a combination of coursework and timed examinations, as described in 4B and 4C above, each with sufficient weight to ensure it is not neglected. This approach has been successfully designed, developed and implemented in many systems over the years and in a variety of ways. The VCE model mentioned in 4C contained all these features—and research showed it led to positive changes in what was taught throughout secondary schools in Victoria.

We have noted that this approach is more expensive than multiple choice tests only if the cost in classroom time spent on otherwise unproductive "test prep" is not included. A system that includes "tests worth teaching to" makes effective use of classroom testing time.

We conclude with comments on two features that have proved important.

The centrality of teacher assessment

An element of classroom assessment by the teacher is crucial. The direct involvement of teachers in assessment enables the inclusion of important, rich kinds of performance that cannot fit within a timed examination—hence coursework. Externally provided coursework tasks and rubrics help teachers become more aware of the nuances of the assessment and the performances assessed.

This complements the element of timed examinations. Most kinds of important performances can be validly assessed through tasks that take less than half an hour, many much less than that. The more tightly controlled and familiar format of a timed examination builds society's confidence in the overall results. But even here there is advantage if teachers take some part as scorers, building knowledge of the exam and a sense of agency—it becomes “our assessment” not just one imposed from on high, in addition to serving as a form of professional development.

In summary, the detailed examination of extended pieces of student work on rich tasks, and the comparative discussions in the monitoring process, are an invaluable contribution to teacher development. The controlled environment of the timed examination builds confidence and allows many aspects of a subject to be covered.

Reporting—the value of multi-dimensional profiles

A fair and valid assessment of any complex subject, including mathematical literacy, must collect a balanced sample of the broad range of knowledge and performance skills that define the domain. Different uses of the results of the assessment will require that information to be condensed to a greater or lesser extent—in the most extreme (and also most common) case to a single number for each student.

The danger in this condensation is that a 1-number score gives a false impression, obliterating the multi-dimensional complexity of a student's abilities in different aspects of the subject. Further, it gives an impression of accuracy that is unwarranted. There is a middle ground where the profile of a student's performance is represented with a handful of scores; in Mathematics, four dimensions are widely accepted as reasonable: separate concepts and skills; extended mathematical reasoning; tackling non-routine problems within mathematics; understanding situations from the real world through modeling and data analysis—the essence of mathematical literacy. Such systems have been demonstrated to be both feasible and psychometrically defensible. Accountability systems based on assessment of this kind can enhance teaching and learning rather than, as too often now, the reverse.

Acknowledgment

The authors gratefully acknowledge the Kaye Stacey's assistance in thinking through the broad range of issues dealt with in this manuscript.

Introduction

Collaborative problem-solving (ColPS)¹ skills are defined as “the capacity of an individual to effectively engage in a process whereby two or more agents attempt to solve a problem by sharing the understanding and effort required to come to a solution and pooling their knowledge, skills and efforts to reach that solution” (OECD, 2017a, p. 6). ColPS skills are prominently featured on lists of 21st-century skills people should possess in today’s fast-changing societies (National Research Council, 2011; Swiecki et al., 2020), as the problems that we face in today’s world have become increasingly non-routine and intractable. Consequently, ColPS skills are considered critical in various dimensions of life, including the workplace, educational and “civic contexts” (Graesser et al., 2018; OECD, 2017a, p. 4; O’Neil et al., 2003; Polyak et al., 2017; Rosen and Tager, 2013; Stoeffler et al., 2020). The significance of ColPS skills even extends to our private lives, such as interactions with our families or among teammates in the sports context (Stadler et al., 2020).

Due to its importance in both everyday life and the workplace, it comes as no surprise that a great deal of attention is placed on assessing ColPS. For instance, it has been included recently in large-scale assessment formats of significance to a broad community of both researchers and policymakers, such as the Program for International Student Assessment (PISA) convened by the Organization for Economic Co-operation and Development (OECD) and the Assessment and Teaching 21st Century Skills (ATC21S).

However, the assessment of ColPS skills does not have a short pedigree. It has evolved at different levels such as measurements at the group or individual level and across various disciplines such as cognitive psychology, business, computer science, education, and other (sub-)disciplines (Andrews-Todd and Forsyth, 2020; Care et al., 2016; Graesser et al., 2018; Oliveri et al., 2017). Since ColPS is related to different disciplines, each with different perspectives and methodological approaches, it is no surprise that the history of ColPS assessment is quite diverse and linked to numerous research traditions.

In a nutshell, the history of ColPS assessment can be described on different levels. That is, there are multiple theoretical perspectives underlying assessments. In addition, various methods have been utilized to measure ColPS, including scoring strategies for processes and outcomes (e.g., Hao et al., 2015; National Research Council, 2011; OECD, 2017a). More specifically, ColPS assessments can be divided into several categories, such as measurements at the group or individual level and at a large or small scale.

Consequently, this book chapter’s overarching aim is to (1) introduce some significant milestones in the development of ColPS assessments, (2) introduce a taxonomy of different assessment approaches, and (3) provide an outlook on the future development (or development needs) of ColPS assessments. Specifically, examining and articulating the levels mentioned above can be beneficial for the further development of assessments, as lessons from the past and the present can serve as a basis for future assessments.

To achieve these aims, in the following sections, we will first discuss various definitions of ColPS by illustrating the similarities and differences between different definitions by means of examples (with a focus on the educational context). We then propose a generic classification framework, which serves as a foundation for classifying different assessment approaches based on methodological aspects and implications. Next, we will illustrate several assessment approaches via examples from the past and the current landscape and connect them with the main aspects of the proposed framework. Finally, we will propose several agenda points to be considered in the future from the perspective of educational psychology and education.

¹Please note that collaborative problem-solving is also abbreviated with acronyms such as CPS in some literature (e.g., Care et al., 2016; Sun et al., 2020).

Definitions of collaborative problem solving

As previously mentioned, there are considerable differences between definitions and perspectives on ColPS. There is still no widely agreed-upon definition or perspective on ColPS (Greiff et al., 2013; Stadler et al., 2020). Many studies intermingle the relevant terms, such as group decision making, teamwork, collaborative learning, and collaborative problem-solving (e.g., Graesser et al., 2018; Kaendler et al., 2015; Oliveri et al., 2017).

On the most basic level, however, existing perspectives and definitions of ColPS share some key similarities. One such similarity concerns the composition of ColPS as a multitude of interrelated (sub-)constructs (Andrews-Todd and Forsyth, 2020; Care et al., 2016; Ercikan and Oliveri, 2016; Hao et al., 2019; von Davier et al., 2017). Here, a construct refers to “the concept or characteristic that a test is designed to measure” (American Educational Research Association et al., 1999, p. 173, as cited in Birk, 2013, p. 4; Care and Griffin, 2014). Another distinct commonality reflected in all definitions of ColPS is that both cognitive aspects (i.e., task work) and social aspects (i.e., teamwork) are required (Avry et al., 2020; Graesser et al., 2018).

However, when taking a more detailed view, differences emerge, particularly with respect to the different facets. That is, the specific sub-skills identified and the frameworks into which they are organized vary considerably (Graesser et al., 2018). For example, the OECD constructed a matrix of collaboration skills and individual problem-solving skills for PISA 2015 (Care and Griffin, 2014; OECD, 2017a). By contrast, the framework for the ATC21S, another large-scale ColPS assessment project, divided each skill into two components, cognitive and social aspects (Care and Griffin, 2014). Meanwhile, von Davier and Halpin (2013) interpret collaboration from a *statistical* viewpoint as “a function of the departure from statistical independence among the activities of two or more individuals” (von Davier et al., 2017, p. 633). Thus, while the PISA and ATC21S approaches highlight “the *types* of interdependence,” this latter approach highlights “the *degree* of interdependence” (von Davier et al., 2017, p. 634). These examples illustrate that various ColPS assessments are built on divergent perspectives.

This diversity of definitions is natural because ColPS is rooted in multiple disciplines and requires cross-functional measurement approaches. Accordingly, it is impossible to settle upon a single correct definition; we should acknowledge the construct’s heterogeneity. In other words, for optimal assessment, we should not distinguish between correct and incorrect definitions, but rather articulate ColPS in a fine-grained way that enjoys broad consent. This is because assessment results stemmed from constructs are in turn likely to derive valid inferences and consequences (see Messick, 1994; Mislevy et al., 2003; Schmidgall et al., 2019).

However, the lack of such a fine-grained and widely agreed-upon definition has not hindered the development of numerous assessment instruments for ColPS. Table 1 provides an overview of examples of CPS assessment, mainly in educational settings. The instruments differ from one another not only in terms of their perspectives but also their methods. Beginning in the next section, we discuss such methodological aspects, another diverse element of ColPS assessments, by means of a classification framework.

A classification framework for collaborative problem-solving skill assessments

To discuss different methodological approaches to ColPS assessment and present an overarching framework for discussion, this chapter draws on classifications by Bunderson et al. (1988), Cope and Kalantzis (2016), and DiCerbo and Behrens (2012, as cited in Shute et al., 2016). Table 2 summarizes these classifications, based mainly on Cope and Kalantzis (2016) and Dicerbo and Behrens (2012) and extended with relevant characteristics from Bunderson et al. (1988). Although these classifications are broad in nature, they can be adapted to ColPS assessments. As seen in Table 2, the classifications focus on methods, particularly with respect to the gradual integration of computer technology. Thus, there is a need to create a custom classification describing the consolidation of computer technology in *ColPS assessments* based on existing generic frameworks. These frameworks can help to categorize progress in the development of ColPS assessments and facilitate improvements to the assessments’ methods or modes.

The framework in Table 2 consists of five *developmental* levels: Level 0 to Level 4. The first level (i.e., Level 0) encompasses traditional assessments with non-computerized tasks and modes. The second level (i.e., Level 1) is characterized by computerized paper-and-pencil modes. The third level (i.e., Level 2) provides test-takers with simulation-based tasks. The fourth level (i.e., Level 3) encompasses natural digital activities. The last level (i.e., Level 4) is characterized by collecting information from different natural digital activities. This hierarchy is utilized in this chapter to categorize and evaluate different assessments. It also highlights a potential point for development, even though not all assessments need to be at Level 4.

Elaborating each level further, Level 0 represents traditional formats of assessments such as paper-and-pencil questionnaires, traditional situational judgment tests, evaluators’ observations, or narratives (e.g., letters of recommendation). That is, assessments at Level 0 are implemented as non-computerized tasks, which mostly consist of discrete items that test only one element at a time so induce limited responses by test-takers. Moreover, assessments are not integrated with other learning activities but are carried out separately.

Next, Level 1 (i.e., computerized paper-and-pencil tests) refers to the simplest transfer of assessments into the “technologically rich environment” (Shute et al., 2016, p. 34). At this level, it is most common for traditional item types (e.g., “discrete, independent items”) to be incorporated into computer environments, although they can have more than one of the following elements: “innovative item types, automated scoring, adaptivity, and/or advanced feedback” (DiCerbo and Behrens, 2012, p. 6, as cited in

Table 1 Example assessments for ColPS and its sub-skills

Example	Field	Inferential level	Method	Description
Behavioral Observation Scales (BOS) (Taggar and Brown, 2001)	Education	Individual	Observation and ratings (likert-type scales)	Anonymous peer assessment of team members' behaviors (e.g., in terms of synthesizing ideas within the team)
Team Problem Solving Assessment Tool (TPSAT) (Rotondi, 1999)	Health and medical workforce	Group	Observation and Ratings	While test-takers participate in simulated performance tasks, an evaluator (potentially their manager) assigns scores between 0 and 100 for each variable
ETS Personal Potential Index (as cited in Oliveri et al., 2017)	Education	Individual	Observation and ratings	- An evaluator assesses students' readiness for graduate school - Parts of constructs overlap with ColPS skills (e.g., teamwork, critical thinking, and problem-solving)
Predictor Situational Judgment Test (PSJT) (Waugh and Russell, 2005, as cited in Oliveri et al., 2017)	Military workforce	Individual	Situational judgment test (paper-and-pencil)	- Written scenarios consisting of 20 items - Utilized for improving the selection and classification of personnel in the United States military - Parts of constructs overlap with ColPS skills (e.g., teamwork, relating to and supporting peers)
Vanderbilt University's Jasper Woodbury Problem Solving Series (Cognition and Technology Group at Vanderbilt, 1992)	Education	Group	Video-based assessment	- Embedded assessment in various content areas (i.e., all the information necessary to solve the problems is included in the video.) - Students need to work together collaboratively (in pairs)
ATC21S (e.g., Griffin et al., 2012)	Education	Individual	Computer-based assessment	- Domain-general - Simulated tasks with human-to-human approach
PISA 2015 (OECD, 2017a)	Education	Individual	Computer-based assessment	- Domain-general - Simulated tasks with human-to-agent approach
ETS Tetralogue (Hao et al., 2015; Scoular and Care, 2019)	Education	Group and individual	Computer-based assessment	- Constructed from a natural sciences perspective (i.e., online simulation in the science domain is provided) - Used in schools for research purposes - Hybrid approach (human-to-human and human-to-agent)

Shute et al., 2016, p. 43). In this regard, Level 1 can be seen as part of the "computerized testing (CT)" or "computerized adaptive testing (CAT)" generations identified by Bunderson et al. (1988, p. 4). According to Bunderson et al. (1988), the CT generation began when traditional tests were converted to computer-based but *non-adaptive* tests. In contrast, the CAT generation led to the emergence of *adaptive* tests that considered students' performance/responses to prior tasks when presenting new ones. In other words, assessments on Level 1 can belong to either the CT or the CAT generation depending on their degree of adaptivity.

Level 2 goes beyond Level 1 by providing more simulation-based tasks (Shute et al., 2016). Test-takers' actions within tasks can be observed via technology, but instruction and assessment are still separated and remain distinguishable from each other (DiCerbo and Behrens, 2012, as cited in Shute et al., 2016). For this reason, assessments at this level still belong to the CAT generation as defined by Bunderson et al. (1988), in which the students' previous responses and the measurement model determine item selection (Quellmalz and Pellegrino, 2009). Moreover, in assessments at this level, item presentation times and test length can change depending on test-takers' previous response times or performance; thus, for assessments at this level, a huge calibrated item bank should be constructed to estimate test-takers' skills (Bunderson et al., 1988).

At Level 3, the line between instruction and assessment is blurred (Shute et al., 2016). In other words, instruction is embedded in the assessment, with both becoming technology-rich activities (Shute et al., 2016). Consequently, the "continuous measurement (CM)" generation begins at this level (see also Bunderson et al., 1988, p. 4). This means that changes or trajectories in students'

Table 2 Classification framework of assessments

	Level 0	Level 1	Level 2	Level 3	Level 4
General description	Non-computerized tasks and modes	Computerized paper-and-pencil CT → CAT generation	Integrated context and tasks CAT generation (continuous)	Lifelike activities with evaluative features in digital environments CM generation	Accrual of information from various lifelike activities in digital environments IM generation
Tasks	Discrete items (i.e., test only one element at a time)	Discrete items	Complex tasks/problems	Complex tasks/problems	Variety of tasks/problems
Integration with learning activities	Low	Low	Low	Moderate	High
Variety of activities/responses	Low	Low	Moderate	Moderate	High
Data type	Traditional assessments (no machine involvement)	Computerized assessments	Structured, embedded data (e.g., semantic tagging and annotation) Unstructured, incidental data (e.g., keystroke patterns, social interaction patterns)		
Mode of data collection	Paper-and-pencil questionnaire, traditional situational judgment test, observation, narratives (e.g., recommendation letters) etc.	Computerized adaptive testing	Natural language processing Procedure-defined processes Argument-defined processes Machine-learning processes Incidental “data exhaust” Dedicated devices for collecting unstructured data		

Note. CT: Computerized Testing; CAT: Computerized Adaptive Testing; CM: Continuous Measurement; IM: Intelligent Measurement.

Cope, and M. Kalantzis, 2016, AERA Open, 2(2), p. 3 (<https://doi.org/10.1177/2332858416641907>). CC BY 3.0.; and “Advances in the science of assessment,” by V. J. Shute, J. P. Leighton, E. E. Jang, and M-W. Chu, 2016, Educational Assessment, 21(1), p. 42 (<https://doi.org/10.1080/10627197.2015.1127752>). Copyright 2016 by Taylor & Francis.

proficiency can be observed and estimated in a continuous and unobtrusive way. For example, students’ strategies (e.g., the methods they use to approach or avoid tasks) can be automatically and instantaneously tested while they complete learning tasks. Moreover, individual learner profiles (e.g., abilities or preferences) can be constructed. Thus, assessments at this level (1) can be more dynamic than the previous levels, which might necessitate more complex psychometric procedures, and (2) focus on “individual purposes, not institutional purposes” (Bunderson et al., 1988, p. 79).

Lastly, at Level 4, assessment data can be accumulated via numerous activities in technology-rich environments that are not limited to only a few settings (Shute et al., 2016). Thus, more knowledge-based computing (i.e., artificial intelligence) can be applied to deal with the mass of information (Bunderson et al., 1988). That is to say, the fourth generation, “intelligent measurement (IM)” would begin at this level with the application of more advanced technologies (Bunderson et al., 1988, p. 4). By using artificial intelligence, more sophisticated individual response processes and trajectories can be automatically measured and interpreted. Furthermore, individualized recommendations can be provided to students and teachers “during continuous measurement,” although scrutiny by professionals should be involved in the case of recommendations with far-reaching consequences (Bunderson et al., 1988, p. 125). Professional guidance may also be crucial because the generated advice can be interpreted or prescribed in several ways.

As will be described in the following sections, an overall trend of ColPS assessments moving from Level 1 to the more advanced levels of this framework can arguably be observed. However, assessments at the lowest level (i.e., Level 0; traditional formats) are still used today as well.

The past landscape

In this section, we discuss ColPS assessments that have been employed in the past based on the framework in Table 2. To evaluate and categorize these assessments, we apply the levels and definitions described in Table 2. In addition, we explore the advantages and disadvantages of several assessment formats, which could be cornerstones for developing optimal assessments in the future (i.e., by helping to identify what to strengthen and what to keep).

As explained in Level 0 of Table 2, most past ColPS assessments were implemented in the non-computerized mode (Dowell et al., 2020; O’Neil et al., 2003; National Research Council, 2011). They were used for selection (e.g., to measure readiness for the workforce/educational institutions), education, and research-related purposes. Specifically for the field of education, several assessment tools were designed and utilized for purposes such as monitoring the development of students’ skills (Kyllonen, 2012). Some examples of assessment formats at Level 0 are mentioned in the *mode of data collection* section of Table 2 and outlined in greater detail below.

- *Self-ratings* (i.e., questionnaire or self-assessment): self-ratings are a popular way to measure inter- and intrapersonal skills, which are components of ColPS skills (Kyllonen, 2012). This assessment format often applies Likert scales or forced choices and asks test-takers in a questionnaire to what extent (or whether or not) they agree with statements about preferences, beliefs, tendencies, and behaviors (Kyllonen, 2012; Oliveri et al., 2017). Some example questions for self-ratings would be “I like to work with people” (Kyllonen, 2012, p. 10), “I helped develop a plan to solve the problem” (Forsyth et al., 2020, p. 404), or “I share ideas with others to accomplish a task” (Stadler et al., 2020, p. 5).
- *Situational Judgment Test*: This type of test confronts test-takers with particular ColPS scenarios (via text or video) and asks them to decide how to react out of a set of plausible options or to rate how appropriate each option is (Oliveri et al., 2017). An example task would be:

Suppose that you find yourself in an argument with several co-workers about who should do a very disagreeable but routine task. Which of the following would likely be the most effective way to resolve this situation?

A. Have your supervisor decide, because this would avoid any personal bias.

B. Arrange for a rotating schedule so everyone shares the chore.

C. Let the workers who show up earliest choose on a first-come, first-served basis.

D. Randomly assign a person to do the task and don't change it.

Stevens and Campion (1999, pp. 225–226).

- *Observation* (ratings by peers/evaluators): Ratings by others are another commonly used assessment format (Kyllonen, 2012). In this format, test-takers' ColPS subskills during real or simulated tasks are assessed based on behavior checklists (Oliveri et al., 2017). That is, external observers note (1) the emergence of (un)desirable behaviors during the task, (2) the quality of behaviors, and (3) their frequencies (Oliveri et al., 2017). For example, evaluators can select a score between 0 and 100 regarding “the process a team uses to explore the problem and to develop a solution” on a simple rubric (Rotondi, 1999, p. 209; see Table 3).
- *Narratives based on biodata*: Narratives such as personal statements or recommendation letters can be utilized to measure a collection of previous life experiences (i.e., biodata), for example, social interaction experiences (Kyllonen, 2012; National Research Council, 2011). Alongside other data, including but not limited to standardized test scores, such narratives can be a tool to assess students' proficiency with respect to particular skills (Kyllonen, 2012; National Research Council, 2011). For example, applicants can be asked to describe a group problem-solving or teamwork experience from their life in personal statements or employment interviews. In such cases, applicants present biodata in order to demonstrate their skills, such as how they solved problems with group members, what difficulties arose, or what the final result was.

The four formats described above have both advantages and disadvantages. As previously mentioned, familiarizing ourselves with these advantages and disadvantages is important, as it can lead us to consider points to be kept or strengthened in future assessments.

Firstly, one advantage of self-assessments is that they are cost-effective and convenient to administrate (Oliveri et al., 2017; Zhuang et al., 2008). Nevertheless, response style bias or reference group bias may influence self-reports (Herde et al., 2019; Oliveri et al., 2017). Also, it is impossible to objectively measure *interactions* between problem-solvers or between tasks and problem-solvers during ColPS with such methods.

Conversely, third-party observation (by peers or evaluators) frees the individual from evaluating him/herself. However, other limitations exist, such as raters' biases and low reliability between different raters. Raters, even when well-trained, are unable to observe all of test-takers' behaviors during assessment. For these reasons, questions remain concerning the objectivity of ColPS evaluations using this method (see Oliveri et al., 2017).

Situational judgment tests can make manifest judgment processes that are normally too subtle to be detected (Oliveri et al., 2017). However, only “procedural knowledge (knowing what to do and how to do)” about effective behavior in the situation can be captured with close-ended response formats, once again leaving questions about the objectivity of the evaluation unanswered (Herde et al., 2019, p. 66; Lievens and Motowidlo, 2016).

Finally, narratives based on biodata can provide additional evidence regarding applicants' skills in the personnel selection context, for example (Kyllonen, 2012). On the other hand, distinguishing skills, knowledge, and cognitive processes is not easy. Also, such biodata may lead to inaccurate predictions about how the applicant will react in future situations, leaving much room for speculation about the real impact of such assessments in terms of criterion validity (National Research Council, 2011).

Table 3 Selected elements of an example simple rubric for “the process a team uses to explore the problem and to develop a solution” (Rotondi, 1999, p. 209).

Scale (from 0 to 100)	
100	The team will break the problem into manageable parts and thoroughly explore each part, in an effort to identify a customer’s particular needs, and the “root causes” of problems. Where appropriate, data will be used to pinpoint problem causes. The team will assess potential problems resulting from interaction of the parts with the whole. A solution will then be developed to address the identified needs and causes of each part of the problem.
40	The team will have a general discussion about the problem. The discussion will jump with no clear plan from one part of the problem to another, and no part will be explored in great depth. Some ideas to solve the problem will be briefly discussed. Finally there will be some debate about how a “standard” approach might be modified to solve this problem.
0	Members will throw out solutions and the team will react to them. The team will not seriously attempt to identify and discuss the possible components of the problem in order to understand it better. The team will basically jump from the problem to a solution. The problem will be solved by using a standard and obvious approach.

Note. Adapted from “Assessing a team’s problem solving ability: evaluation of the Team Problem Solving Assessment Tool (TPSAT),” by A. J. Rotondi, 1999, *Health Care Management Science*, 2, pp. 209–210 (<https://doi.org/10.1023/A:1019004332123>). Copyright 1969 by Kluwer Academic Publishers.

In sum, these traditional methods were (and sometimes still are) the first suitable tools for assessing ColPS for certain purposes. They tend to give a rough estimation of skills *associated* with ColPS, which might have some advantages for both researchers and practitioners, such as generating hypotheses or explanatory analyses. However, these tools tend to neglect the cognitive *problem-solving* part of ColPS. Also, their ability to validly assess real interactions during ColPS is limited due to their methodological pitfalls, such as subjective understandings of scales, as described previously. Hence, in order to appropriately describe and analyze ColPS in its full complexity, other tools need to be applied (Andrews-Todd and Forsyth, 2020; Care and Griffin, 2014; Herde et al., 2019; Quellmalz and Pellegrino, 2009; Yuan et al., 2019). The merely descriptive data on ColPS offered by traditional measures—such as self-ratings, situational judgment, observation, and narratives based on biodata—might have created some reluctance and failure to include 21st-century skills (including ColPS) as an educational objective before the development of more creative and innovative solutions (Kyllonen, 2012).

The current landscape

Leaving the issues associated with assessing ColPS skills with traditional methods behind, technological advances opened new doors for measuring various learner characteristics, including ColPS (Shute et al., 2016). As part of an innovative wave of new technologies, a series of computer-based assessments separated from instruction were developed, which tend to fall into Level 2 or the middle of Level 1 in Table 2 (i.e., computer-based simulations or computerized paper-and-pencil modes).

By implementing simulations with realistic problem scenarios and other computer-based environments, ColPS assessments can capture more complexities of the *interactions* between different individuals as well as between individuals and the computer interface in the form of various types of data. The data used for this purpose include “access-related, response-related and process-related” log data (Kroehne and Goldhammer, 2018, p. 528; O’Neil et al., 2003). Accordingly, current assessments offer measurement opportunities that incorporate social and cognitive aspects (O’Neil et al., 2003).

Broadly speaking, interactions, a core target of such measures, can be divided into two categories in terms of group composition: human-to-agent and human-to-human. Current approaches usually employ one of these two approaches in that they either initiate interactions between a group of human individuals or use computers to simulate some group members. Specifically, the distinction between these two approaches hinges on whether test-takers complete the ColPS assessment in collaboration with pre-programmed computer agents with various characteristics or with real humans such as peers (Rosen, 2015).

Several tools have been developed to measure ColPS using either or both of these approaches. The most prominent implementations were probably those used in ATC21S and PISA 2015 (Hao et al., 2019). Both assessments were interested in domain-general individual ColPS skills and measured them in computer-based simulations (De Boeck and Scalise, 2019; Graesser et al., 2018; Hao et al., 2019; Scoular and Care, 2019).

However, there were also some differences between ATC21S and PISA 2015. One distinctive difference concerns the assessment approach, as stated above (Scoular and Care, 2019). In PISA 2015, a human-to-agent approach was employed, while ATC21S adopted a human-to-human approach (Scoular and Care, 2019). For instance, in the PISA 2015 task *Xandar*, presented in Fig. 1, each student is required to interact with two computer agents in the collaborative setting, such as by proposing a common strategy for solving problems (e.g., “We can answer more questions if we divide them among us,” OECD, 2016, p. 5). As seen in the figure, participants can select from a limited set of pre-defined responses. In contrast, in the example

Fig. 1 User interface for an example unit in the PISA 2015 ColPS assessment, Xandar (OECD, 2016). Note. From Description of the released unit from 2015 PISA collaborative problem-solving assessment, collaborative problem-solving skills, and proficiency levels (p. 4), by OECD, 2016 (<https://www.oecd.org/pisa/test/CPS-Xandar-scoring-guide.pdf>). Copyright 2016 by OECD.

ATC21S task *olive oil*, two students should collaboratively identify and decide on problem-solving tools and processes to achieve the goal of “fill[ing] student B’s jar with 4 L of olive oil,” with each student having different information, resources, and instructions (Care et al., 2016, p. 257). In this task, students’ chats and actions are neither limited nor pre-defined, unlike in the PISA 2015 tasks.

Due to their different approaches (i.e., human-to-agent vs. human-to-human), each assessment had advantages and disadvantages. For example, because it analyzed *real human interactions*, ATC21S has more face and ecological validity, but is more laborious, complex, and time-consuming than PISA 2015 (Andrews-Todd and Forsyth, 2020; Graesser et al., 2018; Krkovic et al., 2018). In contrast, by employing the *human-to-agent* approach, PISA 2015 has higher internal validity, as it was able to construct more standardized problem spaces, which curtail several biases and confounding variables (Graesser et al., 2018). However, due to the limited conversation possibilities, interactions in PISA 2015 are somewhat removed from those in real-life collaboration (Herborn et al., 2020).

After ATC21S and PISA 2015, numerous ColPS assessments inspired by the two assessments, have been conducted by various institutions and researchers. Some trends can be observed in the current landscape of ColPS assessments. Firstly, although such assessments are often implemented at a large scale, only subsets of skills have been focused on due to the multidimensionality and complexity of ColPS. That is, some researchers admit to these limitations and narrow the scope of assessment. For example, the Educational Testing Service (ETS) developed its own assessment tool, ECSAP, and tried to highlight subsets of constructs by studying communication via text chats during collaboration (Hao et al., 2019).

In contrast, other assessments are implemented on a small scale but with more sophisticated analytics, such as machine learning techniques or state-of-the-art devices (Hao et al., 2019). The types of data on collaborative problem-solvers have become increasingly multifaceted, which provides meaningful “evidence of processes such as problem-solving sequences and strategy use” (e.g., time allocation or number of attempts; Quellmalz and Pellegrino, 2009, p. 77). The collected data is analyzed with algorithms to identify characteristics such as different patterns according to expertise (Quellmalz and Pellegrino, 2009). For instance, Polyak et al. (2017) measured individual ColPS ($n = 159$) by applying computational psychometrics—“a blend of data-driven computer science methods, stochastic theory, and theory-driven psychometrics in order to measure latent abilities in real-time” (p. 3)—to data such as log files of “conversation flow” with a virtual agent (p. 5) collected from the tool, *Circuit Runner* of ACT, Inc., an American assessment organization. Recently, Swiecki et al. (2020) proposed the novel method of epistemic network analysis (i.e., “a set of techniques that identifies and measures connections among elements in coded data and represents them in dynamic network models”; Shaffer et al., 2016, pp. 9–10) to measure how an individual’s contribution is related to those of their teammates within a given timeframe and how different it is compared to those of others.

Interestingly, these sophisticated analytics have also been applied to group assessments. Although slightly beyond the scope of the *computerized* generations described in Table 2, it is worth noting here that Fiore and Kapalo (2017) identify three levels of collaborative team assessments (i.e., including individuals and groups) using cutting-edge technologies. At the first level, the micro-level, individual collaboration can be measured through modern neurobiological and physiological technologies such as looking for “neural synchrony” (p. 54) in electroencephalograms. At the second level, the meso-level, interactions between bodies—including “mediating artifacts,” “movements and non-verbal behaviors” (p. 53)—can be employed to study complex constructs (e.g., shared awareness) utilizing technologies such as sensors or “sociometric badges” (p. 4). At the third level, the macro-level, inter-team or inter-network collaboration can be investigated over time using network science and social network analysis. Although the three levels of assessments suggested by Fiore and Kapalo (2017) are not the main focus of this book chapter and beyond the scope of computerized assessments, they can provide us with additional food for thought concerning the wider scope of technologies (i.e., not only computers but also various evolving devices and techniques) for future research.

Alongside these (at the moment still rather) philosophical considerations, the endeavor to refine assessments has continued. For example, educational researchers are illuminating complex constructs empirically or devising scoring methods for group/individual assessments beyond traditional test theories. For example, Andrews-Todd and Forsyth (2020) outline an ontology of ColPS constructs composed of multiple layers of concepts, behaviors, or strategies that identifies a hierarchy of skills (i.e., high- or low-level) while specifying how evidence for them can be collected from log data. In doing so, the ontology identifies explicit evidence that can be used to infer students’ skills (Graesser et al., 2018). In terms of scoring, von Davier and Halpin (2013) investigate several statistical models to measure individual ColPS with process data, such as Bayesian knowledge tracing or hidden Markov models, and introduce an alternative model for measuring individual cognitive skills during ColPS. They claim that their novel model is distinct in that individual latent ability, individual actions, and entire process trajectories during ColPS are all conditions of the model.

It might be too early to claim to have provided a full account of these current streams in ColPS assessment, as most approaches are still in their infancy. However, some consequences of the assessments employed in ATC21S and PISA 2015 can already be identified. PISA 2015 led to unexpected consequences due to innate characteristics such as the use of a standardized test across nations and the publication of results based on a ranking system. For instance, in contrast to the original intention, few educational reforms to cultivate students’ ColPS skills took place following PISA 2015, particularly in high-ranking countries (i.e., off-label use of the assessment, Zumbo, 2015). Although the ATC21S project was launched to offer feedback to stakeholders (i.e., not only students and teachers but also schools and systems; Griffin et al., 2012), the results may also have somewhat deviated from the original intention in practice. Poon et al. (2015, p. 204) report the following vignettes from a teacher and a student participating in the project in Singapore:

I do not see any formative feedback given to students in the task. Students are not aware of whether they got the answer right or wrong, and how do they improve based on the mistakes they have made in solving the questions? (Teacher).

I received no feedback (Student).

Nevertheless, more empirical evidence is needed in order to evaluate the impact of current ColPS assessments on educational policies and curricula. What can be highlighted is that despite several limitations and unintended repercussions, ATC21S and PISA 2015 made laudable, ground-breaking progress and set the foundation for subsequent research on such assessments (Hao et al., 2019; Poon et al., 2015).

Future directions and agendas

The importance of ColPS in the 21st century is undisputed. Despite the introduction of new technologies and a growing body of research on ColPS using a variety of tools, there remain open questions to be tackled in order to further develop ColPS assessments toward or beyond Levels 3 and 4 (i.e., amassing information from various lifelike activities in digital environments; see Table 2). In other words, this will allow evidence on ColPS to be collected in manifold settings simultaneously and instantaneously integrated with learning activities. Moreover, the collected data will be analyzed more elaborately with the help of innovative technologies.

One way to approach this goal is cooperation on an interdisciplinary level. The field of ColPS assessment can benefit from research from multiple perspectives in the form of great insights on multilevel analysis and a deep understanding of such assessments (Fiore and Kapalo, 2017). For instance, although current artificial intelligence technologies have limitations for studying

human-to-human collaboration, it is recommended that psychologists work with the developers of such technologies (Graesser et al., 2018; Hao et al., 2019). Such collaboration will assist in the automatic, multilevel analysis of larger samples while ensuring measurement validity (Graesser et al., 2018). It can also result in empirical studies in the human-to-human as well as human-to-agent modes.²

Another way of advancing the field is to continue revamping and optimizing existing assessments in sophisticated ways (Krkvic et al., 2018). First, appropriate methods such as Bayesian logic should be explored more deeply to solidify “evidentiary arguments” such as those based on the evidence-centered design (ECD) framework (Mislevy et al., 2003, p. i; Shute et al., 2016). The ECD framework is a well-known logical approach to constructing a test with valid reasoning while eliciting the target assessment constructs, obtaining evidence from students’ behaviors, and creating tasks to elicit such evidence (Mislevy et al., 2003; Shute et al., 2016; Zieky, 2014). In addition to studying ColPS constructs, the effectiveness of assessment task design can also be examined (Lin et al., 2015). Specifically, tasks should be constructed such that they optimally elicit the target constructs and cover the levels of proficiency defined in the ECD framework. A study Child and Shaw (2016) fleshes out this point by identifying five task design criteria for ColPS assessments: (1) sufficient complexity, (2) ill-structured tasks, (3) use of technologies to facilitate the ColPS process, (4) dynamics (including negotiation) among team members, and (5) team members’ motivation for collaboration. An additional suggestion is (6) use of technology to *explore* the ColPS process. For instance, strategic behaviors (e.g., how to share information) can be highlighted through the pattern of turn-taking among problem-solvers (Krkvic et al., 2018). In addition, tasks are authentic when they involve “the challenges and standards of [real-world] performances” (Wiggins, 1989, p. 703) and “the ways in which knowledge and skills are used in real-world contexts” (Frederiksen and Collins, 1989, p. 30) despite the underrepresentation of complex “functioning” in the real-world ColPS situation (Messick, 1994, p. 17). What and how to score such assessments should also be studied more extensively, particularly given the quantity and variability of mass data collected by technologies, which includes final outputs as well as processes (Scoular et al., 2020).

Furthermore, further empirical studies should be conducted to disentangle social, cognitive, and metacognitive aspects of the ColPS framework or investigate influencing factors. This idea is associated with building a common understanding of ColPS and consequently obtaining more valid results from data collected in multiple settings. In addition, such research can influence policy-makers to identify ways to facilitate students’ education based on the results of assessments embedded within learning activities. For instance, the PISA 2015 ColPS assessment results indicate that girls tend to outperform boys, which is influenced by disparities in personality traits (i.e., “more agreeable and more conscientious”; OECD, 2017b, p. 93). As this case demonstrates, discerning factors that influence ColPS assessment scores can not only increase flexibility in enhancing students’ ColPS in education contexts but can also lead to the construction of more valid assessments.

Finally, there is a need to increase the level of acceptance and understanding of ColPS assessments in educational settings. If teachers, students, and other stakeholders do not have a good understanding of what such assessments measure and how they can be interpreted, even good assessment tools cannot be implemented sustainably and integrated into learning. According to Poon et al. (2015), Singaporean teachers who participated in ATC21S had trouble with “concepts in the new teaching and assessment paradigm—including the introduction of ambiguity into assessment tasks, tracking dynamic behaviors in collaborative settings, and the debate over content-rich and content-free assessment of 21st century competencies” (p. 199). To alleviate these difficulties, professional development opportunities for teachers and relevant stakeholders on ColPS assessments should be promoted more strongly, and students should be given sufficient opportunities to familiarize themselves with the new assessments.

The journey to more advanced levels of assessment might be quite arduous. However, concrete plans to cultivate students’ ColPS can only be studied once a thorough understanding of ColPS skills, processes, performance levels, and measurement has been achieved (Krkvic et al., 2018). Despite the already observable shift away from non-computerized assessment, considerable work still needs to be done in order to reach this goal. Once a more mature level of understanding based on enhanced assessments has been achieved, not only national policies but also personalized learning strategies or interventions to foster ColPS can be crafted based on a stronger evidence base.

There is a belief that ease of measurement often dictates which subjects are assessed, and “hard to measure” subjects are ignored. Assessment and measurement are in turn seen as reducing learning and curriculum to what is easy to measure. In fact, nothing is too hard to measure. As [Thurstone \(1959\)](#) said, “If it exists it can be measured, and if it can’t be measured it doesn’t exist.” It all depends on how measurement is defined and how we organize the evidence of more difficult learning concepts.

[Griffin et al. \(2012, p. 10\).](#)

Introduction

The transition from the 20th to the 21st century has diverted increased attention toward the societal changes and transformations that have taken place over the last two decades. Change and transformation have become buzzwords indicating how our societies are adjusting to the contemporary and future challenges of labor markets, economic models, education and the environment ([Hölscher et al., 2018](#)). However, there is no agreement concerning what change and transformation really mean in policy and practice, which leaves an open discourse about how to define key parameters for such development in education. Further, the most important driving force for these perspectives has been the technological developments that have taken place during this period ([Mahlow and Hediger, 2019](#)). Technological developments and innovations—along with increased access to them—and media culture have created entirely new conditions for communicative interaction, information flow, creation and so forth ([Mahlow and Hediger, 2019](#)).

In this chapter, we focus on the educational assessment of 21st century skills, aiming to put forward critical issues related to the assessment of such competence areas and frameworks in contemporary societies. 21st century skills frameworks have become important international policy directives, transforming curricula in many countries over the last decade. However, there is uncertainty surrounding how to understand and measure such skills. To move forward, there is a great need to systematize our knowledge and experiences in this area.

We start by introducing some definitions of 21st century skills, addressing theoretical and empirical perspectives and issues. We also provide a short overview of key transformations in educational assessment and an outline of international and national initiatives, using examples from two countries, Norway and Finland. In the next section, we present some examples of projects and assessment instruments relevant to our argument that assessment, education and technological development has to be defined as interrelated parts of how to understand and assess 21st century skills. In the last section, we detail some perspectives on assessments and transformations in education that point toward opportunities and pitfalls for the future. By taking a meta-perspective, we identify evolving themes within this field and provide a critical perspective on further developments.

Defining 21st century skills

Education has been defined as a key mechanism for providing future citizens with the qualifications and competences needed for life in the 21st century ([Ananiadou and Claro, 2009](#)). Instructing 21st century skills has thus become a key initiative, especially over

the last decade, and part of the educational policy agenda (Tahirsylaj and Sundberg, 2020). Different frameworks have been presented, and such skills have now entered curricula in many countries (Erstad et al., 2021). There is not a clear consensus on what defines such frameworks, but some key concepts and terminology are common across most of them (Joynt et al., 2019). While some have criticized the focus on 21st century skills as reliant on the metanarrative of “salvation through technology,” primarily informed by human capital theory or similar schools of thought that reduce student identity by praising homogenizing practices (Hilt et al., 2019), others have welcomed it as a vital part of a knowledge-based society (Voogt and Roblin, 2012).

A number of definitions have been proposed to pin down what exactly 21st century skills are. Nearly all the definitions emphasize their importance for individuals, society and future work life (Siddiq, 2016). In the following, we provide three definitions of 21st century skills. These examples were chosen because they are the most cited sources in related frameworks and definitions (Tahirsylaj and Sundberg, 2020). The first is provided by the Organization for Economic Co-operation and Development (OECD) and defines 21st century skills as “those skills and competencies young people will be required to have in order to be effective workers and citizens in the knowledge society of the 21st century” (Ananiadou and Claro, 2009, p. 8). The second is proposed by the Partnership for 21st Century Skills (P21), stating that they are “the skills, knowledge and expertise students must master to succeed in work and life—a blend of content, knowledge, specific skills, expertise and literacies” (2010, p. 8). The third is provided by the Assessment and Teaching of 21st Century Skills (ATC21S) project, which asserts that 21st century skills are underpinned by knowledge, skills, attitudes, values and ethics—referred to as the KSAVE model (see the next section for more on this initiative) (Binkley et al., 2012).

In a recent systematic review, Tahirsylaj and Sundberg conclude that “there is still unfinished business for educational researchers in critically engaging with framing and defining competences for the 21st century” (2020, p. 1). Acknowledging this need, we also agree with scholars in the field that 21st century skills are broad, complex and generic (Geisinger, 2016). They refer to a wide range of competences, attitudes, values and ways of working that are cross-curricular and changing alongside the developments and transformations brought by technology. A number of initiatives further unpack and detail 21st century skills, identifying the most common ones as collaboration, communication, ICT literacy (also labeled digital competence or digital literacy; Siddiq, 2016), citizenship, problem solving (reference to Greiff in the Encyclopedia), critical thinking, creativity and productivity (Geisinger, 2016; Voogt and Roblin, 2012). Note that some frameworks also mention learning to learn, self-direction, adaptability, mathematics, science, history and art (Voogt and Roblin, 2012). We note that even though the study by Voogt and Roblin was conducted almost a decade ago, it is still relevant and often referred to. Most importantly, to our knowledge, no update to its comparative analysis of 21st century skills frameworks has been published. In the following section, we provide an overview of some of the evolving 21st century skills frameworks that have laid much of the foundational focus and emphasis on these skills in education and we discuss how assessment has become a key aspect of such frameworks.

Evolving frameworks of 21st century skills

A key initiative that has been influential for the way policy makers and researchers address challenges and transformations for education in the 21st century is the Definition and Selection of Key Competencies (DeSeCo) project, which the OECD began at the end of the 1990s, about the same time as the Program for International Student Assessment (PISA). A group of researchers and experts were brought together to discuss the concept of “competence” and how it relates to social processes of transformation, as well as “cross-curricular competencies” as the “knowledge and skills related to outcomes of education in a broad sense” (Salganik et al., 1999, p. 13). The authors of the DeSeCo reports mention that concepts like “competence” and “skills” are quite vague. Their approach focuses on the complex challenges that young people today face when entering work and life, indicating that the notion of competencies encompasses cognitive but also motivational, ethical, social and behavioral components, combining stable traits, learning outcomes (e.g., knowledge and skills), belief–value systems, habits and other psychological features. Basic reading, writing and calculating are thus skills that make up the critical foundation of numerous competencies. That is, 21st century skills are wider than pure subject knowledge; they are multifunctional, multi-faceted and inter-related, consisting of several competencies and sub-competencies (Griffin et al., 2012; Tahirsylaj and Sundberg, 2020; Voogt and Roblin, 2012). Rychen and Salganik (2001, p. 8) emphasize that they are “transversal across social fields and refer to a higher order of mental complexity.” In particular, understanding what these skills are is utterly important from an assessment perspective, which has traditionally focused on one single subject at a time (Siaorova et al., 2017). We do not hold the view that assessment within a single subject is easy or effortless. Rather, our viewpoint is that 21st century skills frameworks and issues have added several dimensions to the assessment field.

In 2006, the European Commission published the Key Competences for Lifelong Learning: a European Reference Framework (European Parliament, 2006). This framework of key competences was revised 10 years later and implemented in 2018 with an increased focus on 21st century skills. Eight key competences are outlined therein as necessary for personal fulfillment, active citizenship, social cohesion and employability. These competences are: (1) literacy; (2) multilingualism; (3) numerical, scientific and engineering skills; (4) digital and technology-based competences; (5) interpersonal skills and the ability to adopt new competences; (6) active citizenship; (7) entrepreneurship; and (8) cultural awareness and expression.

The Key Competences Network (KeyCoNet) project, organized by the European Schoolnet (Looney and Michel, 2014), brings together definitions and initiatives surrounding these key competences, especially digital competence. One report, based on surveys conducted across Europe, shows that many countries struggle in their efforts to implement such competences into school curricula (Arjomand et al., 2013). Curricula developers and schools have a tendency to focus on competences that are familiar, like STEM and mother tongue and foreign language learning, while more unfamiliar and complex competences, like creativity, collaborative

problem solving and digital competence, are not implemented in the compulsory curriculum. Moreover, the assessment of such competences is oftentimes not addressed (Care et al., 2018a,b). The reason for this oversight is a key area to address in order to understand future possibilities and tensions in educational assessment of key competences and 21st century skills.

An important initiative in this field is the Assessment and Teaching of 21st Century Skills project (ATC21S) (Griffin et al., 2012). This is a unique project in the sense that it not only identifies and defines 21st century skills but also focuses on assessment as a core part of its mission. One of the working groups, of which Ola Erstad was a core member, published a white paper, which later became a book chapter, called “Identification and definition of 21st century skills.” This group identified ten skillsets defining 21st century skills, grouping them into four areas: ways of thinking (1. creativity and innovation; 2. critical thinking, problem solving, decision making; 3. learning to learn, metacognition); ways of working (4. communication; 5. collaboration, teamwork); tools for working (6. information literacy; 7. ICT literacy); and living in the world (8. citizenship—local and global; 9. life and career; 10. personal and social responsibility—cultural awareness and competence). What is unique to this project compared to other national and international frameworks from this time is that each skillset is operationalized according to its components: knowledge, skills, attitudes, values and ethics, thus called the KSAVE model (Binkley et al., 2012, p. 37).

These frameworks have set the agenda for instructing 21st century skills and the future orientation of education systems around the world. In the next sections, we will focus on more concrete examples of how these frameworks have been addressed before returning to overall perspectives of transformation and change as part of the educational assessment of these skills. One fundamental difficulty is that of gathering information on assessment of 21st century skills in non-European contexts. For example, the International Computer and Information Literacy Study (ICILS), across three cycles (2013, 2018, 2023) has no representation from African countries and an overrepresentation of European countries.

From policy to practice

Central to how the assessment of 21st century skills is implemented and explored as part of learning practices is the way curricula specify how such skills should be integrated into teaching and instruction—in which subjects and on which levels. Curricula are the tools through which policy makers influence practices. Over the last 5–6 years, new curriculum developments have emerged in several countries, referring to what they call 21st century skills and reflecting on the ways that teachers conceive of assessment as part of the process of developing such skills and as being linked to the digitalization of schools. However, surprisingly, not much has been written about how digital technologies transform the development and content of curricula for schools (Williamson, 2013; Erstad et al., 2021).

We will here introduce some recent developments in the countries we know best and focus on assessment in the next part. Within the Nordic region, Norway and Finland are the countries that have most explicitly referred to 21st century skills in recently updated curricula inspired by the contemporary frameworks mentioned above. Interestingly, the ways in which these two countries have dealt with such skills when developing new national curricula are slightly different.

In Finland, a re-orientation of the school system has been implemented through the new National Core Curriculum of 2016 (Finnish National Agency for Education, 2016). One of its main goals has been to enhance competence building and the development of 21st century learning skills among students (Erstad et al., 2021). The rationale for this re-orientation is that the world is changing rapidly; the school system needs to evolve to meet the needs of the future while still enabling equal opportunities. Even though Finland has scored high on international tests like PISA (OECD), policy makers have identified several challenges emanating from major societal, demographic, cultural and economic changes. This recognition has pushed forward a sense of urgency in building a school system oriented toward the future. One study clarifies that the new educational curriculum in Finland holds the view that “the purpose of education is to promote life-long and life-wide learning, holistic development and well-being of all learners, as well as to improve their skills for living in a sustainable way” (Halinen, 2018, p. 75).

One of the main intentions of this curriculum reform was to promote an integrative approach to teaching and learning. The purpose of this approach was to enable students to see the relationships and interdependencies between the subjects studied at school and the phenomena of life outside school (Halinen, 2018, p. 84). The most important tools for this purpose, defined in the core curricula, are transversal competencies, multi-disciplinary learning modules and pupil assessment. These “transversal competences” are developed by all subjects and are based on the Act on Early Childhood Education and Care and the National Core Curriculum for ECEC (2018). These competences are:

- (1) Thinking and learning to learn
- (2) Cultural competence, interaction and expression
- (3) Taking care of oneself and managing daily life
- (4) Multiliteracy
- (5) Digital (ICT) competence
- (6) Working life competence, entrepreneurship
- (7) Participation, involvement and building a sustainable future

These seven transversal competences have been taken into account when defining the objectives and main content areas of compulsory school subjects. Moreover, the content load has been reduced in all subjects to allow for more depth in understanding of domain knowledge and spend time on transversal competences. The subject descriptions also point out the links between the objectives of the subject and the objectives of the transversal competences.

Interestingly, these transversal competences are not defined as 21st century skills specifically, but rather as broader principles of learning and literacy. Still, they are framed within conceptions of 21st century skills and the changes necessary within schools to meet future challenges.

Assessment has also been included in this strategy to transform the methods through which schools support a more integrative approach to teaching and learning. As stated by Halinen (2018): “In Finland, especially in basic education, the focus is on formative assessment and giving supportive and encouraging feedback. In addition to the assessment of learning, more and more assessment for learning and assessment as learning takes place. The development of skills for self-assessment and for peer-assessment is promoted during the school years. This means that students learn step by step, and are supported by their teachers, to set goals for their own learning, to discuss the assessment criteria, to plan and reflect upon their working processes, and to assess the results of their own work” (2018, p. 86). Halinen (2018) also makes the point that “in Finland, we seldom use the phrase ‘implementation of the curriculum’ but instead talk about teachers who construct their own professional guidelines based on the local curriculum. They are the ones who bring the curriculum into reality” (p. 87). However, a system and tools of assessment that fulfill these objectives for schools are still in development.

In Norway, the process of revising the national curriculum started with a broader process of exploring a framework for future schools in Norway, led by a governmental committee consisting of researchers, stakeholders and representatives from the field of practice but also involving teachers and school leaders around the country through a blog. This process produced a lot of engagement from teachers with suggestions about a revision of school subjects. As part of preparing for the new curriculum, the governmental committee commissioned a systematic review of research and frameworks on 21st century skills, led by Prof. Erstad. This work summarized common concepts and frameworks across the literature by defining ten key concepts therein. The committee further used this review in writing up a green paper for the government (NOU, 2015). In this green paper, they define four key areas, described as future competences, that should be included in all subjects. These areas are:

- Subject-specific knowledge
- Competence in learning
- Competence in exploring and creating
- Competence in communicating, cooperation and participation

However, in writing up the final curriculum, the Renewal of the Subjects (“Fagfornyelsen,” White Paper, 2016), these competence areas are not defined; the focus is rather on how the subjects can be renewed. Moreover, these areas are integrated into principles for learning, development and *Bildung*. The term *Bildung* refers to the German concept of self-cultivation, to become literate/educated, and the process of formation as a lifelong process of becoming human (Siljander and Sutinen, 2012). *Bildung* corresponds to the Humboldtian (1767–1835) model of higher education of spiritual and cultural growth, and refers to both a *process* and *outcome* in developing a person through education (Schneuwly and Vollmer, 2018). This tradition has been criticized for being too elitistic, and during the last two decades attempts have been made to re-write conceptions of *Bildung* better suited for the digital age. Hence, in lack of an equally comprehensive concept, Digital *bildung* has been introduced. Digital *bildung*, among others, focuses on how students’ participation, multi-membership of different communities and identity development in the digital era are influenced by the digitization of society. This implies ethical and moral reflections on the technology’s role in human development (Krumsvik, 2008).

In the Norwegian curriculum *Bildung* traditionally is important for the overall aims of education. Recent curriculum developments privilege a connection between basic skills to prepare students for the future and certain aspects of schooling, such as three key trans-disciplinary themes (democracy and citizenship; sustainable development; public health and coping with life) and the specific principle of deep learning. This focus has garnered a lot of interest from teachers, but it is not clear what these themes actually mean in practice nor the conceptual understanding of deep learning. Another important new aspect of the national curriculum is its emphasis on computational thinking and programming, which also brings new aspects to the framework of 21st century skills that need consideration for the purpose of assessment.

Curriculum developments in Finland, Norway and other countries point to the existence of important challenges in implementing 21st century skills frameworks from policy to practice. In both national curricula, assessment is defined as very important in supporting students’ learning. However, they are vague in explaining how assessment is embedded in instruction of 21st century skills, and they do not give any indication about a renewal of the assessment system tuned to future challenges and new orientations toward skills and competences.

Assessment in the 21st century—digitalization

Assessments serve many functions within education systems, motivating and helping students to learn and assisting teachers in refining their practice and supporting their students’ learning. Some additional functions include certifying student accomplishments, evaluating the output of educational programs, measuring the progress of educational systems, and facilitating cross-national comparisons (OECD, 2013). Linked to students’ learning, assessment is often divided into two main categories: formative assessment, understood as “assessment for learning,” and summative assessment, understood as “assessment of learning” (Siarova et al., 2017; Boitshwarelo et al., 2017, James in Encyclopeida). While formative assessment is undertaken throughout the school year and functions as feedback for the student to increase learning, summative assessment is often conducted at the end of the

learning cycle (e.g., at the end of the school year or semester). The latter is often high stakes, constituting the students' knowledge in the form of a grade, which may impact their future plans. Some researchers emphasize a third approach toward assessment, "assessment as learning," which extends the use of formative assessment for learning and is considered a process through which students are largely involved in the assessment, playing a key role in their learning (Dann, 2002).

In the field of digitalization and the transformation of education and assessment, increased attention has been paid to developing new and improved instruments to assess new competence areas. Nevertheless, this field is still very much in development, and there is a basic challenge in adjusting both formative and summative assessment strategies to be more in tune with the needs of education systems concerning new areas of skills and competences among students. An important dimension to this shift is the role of digital technologies and the assessment of 21st century skills. Technological developments can facilitate innovations and alternative approaches to assessments (Siarova et al., 2017). Even in a key international journal like *Assessment in Education: Principles, Policy & Practice*, there are not many articles that target assessment and digital technologies specifically. There is an interesting special issue from 2003 in the sense that it addressed important issues of technology and assessment early in the 2000s when technologies were starting to enter schools on a large scale and that this is an important journal in the field setting the agenda for such issues in this field of research. During the early 2000s there are not many other articles or journal issues with the digital dimension as a core focus. However, after this special issue an important development was how ways of using digital technologies became associated with key skills development of the 21st century, both as part of the above-mentioned frameworks, and as opportunities to transform assessment methods in fundamental ways (Griffin et al., 2012; van Laar et al., 2017).

Revisiting an article written by Erstad (2008), which summarizes issues surrounding assessment practices and the role of new technologies therein, it is clear that a major concern in much of the research at that time was the transition from paper-and-pencil to computer-based assessment. Several studies trying to compare these testing methods describe the latter as highly problematic, especially concerning issues of test validity (Russell et al., 2003). However, since 2008, most assessments have shifted to using computers and including digital interfaces, while paper-and-pencil tests are less common in most countries. Furthermore, the assessments—in particular summative assessments—have largely moved from being driven by individual teachers and schools to being derived from national tests and international studies, like PISA and the Trends in International Mathematics and Science Study (TIMSS).

However, as described then (Erstad, 2008), it is still possible to see three combinations of assessment and digital technologies. First, such technologies can be used to make traditional tests and assessments more efficient, since data can be processed using digital software. Second, digital technologies are used to assess competences and areas that traditionally have been difficult to assess and to develop new instruments and approaches. Technological developments have created a new interest in what some describe as "assessing the inaccessible" (Nunes et al., 2003), like metacognition, learning strategies, attitudes and lifelong learning skills (Anderson, 2008; Deakin Crick et al., 2004; Siddiq et al., 2017). These innovations have promoted the use of formative ways of assessment in order to better monitor and assess student progress through different modes of expression (multimodality). An important point is also the way digital tools can support collaborative work. Students can send documents and files to each other and, in this way, work on tasks together. Within the field of computer-supported collaborative learning (CSCL), there are many examples of computer-based learning environments designed for collaboration to stimulate student learning and the process of inquiry (Wasson et al., 2003). Such collaborative problem-solving skills are considered necessary for success in today's world of work and school. Online collaborative problem-solving tasks offer new measurement opportunities when information on what individuals and teams are doing is synthesized along the cognitive dimension. This development raises issues both about interface design features that can support online measurement and how to evaluate collaborative problem-solving processes in an online context (O'Neil et al., 2003). There are also examples of web-based peer assessment strategies in ways that students themselves are put in the position of evaluators as well as of learners (Lin et al., 2001; Lee et al., 2006). Third, digital technologies can be used to test digital skills specifically. Since digital skills and competences have become key elements of national curricula over the last decade, as we will return to below, the challenge has been to develop items and instruments for assessment of such new competence areas (see **Case 2: Assessment of computer and information literacy**).

Another dimension that has entered the field of assessment and digital technologies in the last decade is that of "learning analytics." The development of online environments and participation, also referred to as "platformization" (Sefton-Green, 2021), means that digital data has become a new resource for the assessment of skills such as online reading, writing and collaboration, self-regulated learning over time, creativity and lifelong learning. Digital data also provides information about how students navigate and click within online environments as part of solving tasks, thereby visualizing how students solve tasks, individually or in collaboration, and where they may have problems. Enormous amounts of data are collected as part of educational online platforms linked to basic and higher education, as well as in Massive Open Online Courses (MOOCs) and throughout our everyday lives. However, how we can systematically collect, analyze and visualize data generated by digital tools as part of assessment activities is still being investigated (Cui et al., 2020). After years of over-optimistic arguments about the possibilities provided by data tracing and gathering for creating affordances for students' learning processes, this field seems to become more nuanced in what can actually be done in approaches toward "big data," along with digital tools that need to be developed to make sense of the vastness of the available data and how it might help us in developing new tools and approaches to assess 21st century skills. Moreover, as highlighted by Murchan and Siddiq (2021) there is a critical need to address ethical and privacy issues related to use of process data in educational assessment.

International assessment initiatives

Acknowledging that issues of educational transformations, and specifically those related to 21st century skills frameworks and assessment practices, are still in development, it is all the more important to point out the main challenges and learn from previous experiences. In this section, we will present some international initiatives that have developed instruments and practices for assessment. We identify two competence areas within these frameworks, namely digital competence and collaborative problem solving, and focus on them as cases through which to illustrate developments in assessment instruments, approaches and research linked to educational practices. After these case presentations, we will also briefly describe three ongoing projects to demonstrate how former international initiatives are now being followed up with new national projects in this field. There are of course other relevant examples internationally, but we concentrate on those that we know well as illustrations of further developments.

Case 1: Assessment of 21st century skills (ATC21S)

The team behind the above-mentioned ATC21S project (Griffin et al., 2012) wanted to follow up on the initial framework and perspectives to develop more concrete tools for the assessment of 21st century skills. Two institutions took part—the Assessment Research Center at the University of Melbourne, Australia and the Berkeley Evaluation and Assessment Research (BEAR) Center at UC Berkeley, USA. They identified two competence areas, combining several of the skillsets in the initial framework, to be assessed on a broader scale internationally. They aimed at measuring collaborative problem solving (including a combination of critical thinking, problem solving, decision-making and collaboration) and digital literacy through an assessment they called the Learning through Digital Networks—ICT Literacy Test, which evaluates the competence areas of information literacy, ICT literacy and personal and social responsibility within the 21st century skills framework. The team, together with international scholars, initialized and developed two main assessment instruments that were piloted in six countries (Australia, Costa Rica, Finland, Netherlands, Singapore and USA), and they reported their experiences in a book series (Care et al., 2018a; Griffin and Care, 2015).

Given our focus in this chapter, it is interesting that these 21st century skills were conceptualized as an outline for developing assessment instruments and approaches. Collaborative problem solving was understood as consisting of five broad strands (see Fig. 1) and was defined as the capacity of an individual to recognize the perspectives of other persons in a group, participate as a member of the group by contributing their knowledge, experience and expertise in a constructive way, recognize the need for contributions and how to manage them, identify structure and the procedure involved in resolving a problem and, as a member of the collaborative group, to build and develop knowledge and understanding. In the process of creating and field-testing collaborative problem solving tools, broad types of scenarios and tasks were developed and trialed (Fig. 1).

The learning through digital networks—ICT literacy competence was conceptualized as consisting of the following strands: learning as a consumer of information; learning as a producer of information; learning in the development of social capital; and learning in the development of intellectual capital (Griffin and Care, 2015). Several broad scenarios were developed that engaged up to four students at a time in identifying procedures and collaborative tools that enabled them to learn and develop (see Fig. 2).

For these two skill areas, the assessment tasks were checked with teachers to ensure that they were realistic, that students would be able to work with them, that they could differentiate between high and low levels of ability, and that the skills underpinning the task resolutions were teachable. Think-aloud protocols were used in small-scale studies (cognitive laboratories) with students representing the target population in order to generate bases for the automatic coding and scoring of student performances on the tasks. A series of small-scale pilot studies were undertaken in a small number of intact classes to determine the technological and administrative requirements for assessment implementation. These studies represented a rehearsal for the large-scale trials that were carried out in the above-mentioned six countries. Trial data was collected using a matrix sampling approach to identify a uniform cross-national sample of students to maximize calibration accuracy (Care et al., 2018a,b; Griffin and Care, 2015).

Since the ATC21ST project ended its funding period in about 2013, several smaller national and international groups have continued working with the two assessments. The Melbourne group has kept their focus on the assessment of collaborative problem solving by further developing tasks within this assessment framework alongside methods and practices for analyzing such data,

Fig. 1 Conceptual framework for collaborative problem solving (Griffin et al., 2012).

Fig. 2 Conceptual framework for learning in digital networks (Griffin et al., 2012).

while still disseminating knowledge gained from the continued project (e.g., Pöysä-Tarhonen et al., 2018; Scoular and Care, 2019, 2020).

The assessment of digital literacy also garnered continued attention by Fazilat Siddiq and others (Siddiq, 2016). Siddiq translated, adapted and revised the learning through digital networks—ICT literacy test, piloting it in the Norwegian educational context to investigate its validity and reliability (Siddiq et al., 2017). She also published a second study adding a novel task aimed at assessing students' collaborative problem solving (Siddiq and Scherer, 2017). In both these studies, it was apparent that it was not sufficient to score the students' responses to the tasks as correct or incorrect. To gain a further understanding of students' competence within the underlying domains and to assess these constructs authentically, it was also necessary to investigate and score the processes by which the answer is reached (e.g., following which paths they took through click streams). In sum, technology offers new opportunities for assessing the 21st century skills that could not easily be detected in paper-pencil assessments. At the same time, it also creates new challenges that needs to be dealt with, such as determining which patterns of movement within a test environment should be scored and what it would mean to leave them out.

Case 2: Assessment of computer and information literacy

The only international, large-scale assessment of digital literacy and 21st century curricula is The International Computer and Information Literacy Study (ICILS) developed and conducted by IEA (International Association for the Evaluation of Educational Achievement). ICILS measures and monitors developments and changes across time in students' computer and information literacy achievement and their home and school environments with regard to access to technology, use and support of digital literacy in classrooms (Fraillon et al., 2014). The assessment consists of both questionnaires about technology use among different stakeholders (e.g., teachers, principals) and a performance assessment. For the participating Nordic countries (Denmark, Norway and Finland), the study reveals a high rate of access to technologies both at school and at home compared to other countries, as well as higher performance on most of the items on the ICILS scale (Fraillon et al., 2014). The study also reports similarities in the impact of students' socio-economic background and gender—girls performed better than boys on most items—on the results. Nordic teachers are more positive about using digital technologies compared to many other participating countries; however, a majority of students report that such technologies are not used much in learning activities in subject domains, even though a majority of students use them at large at home (Fraillon et al., 2014).

ICILS was initiated in 2013 and runs every 5 years. Even though this large-scale assessment provides education systems and policymakers with important knowledge on the contexts and outcomes of CIL-related education programs, the participating countries vary. More importantly, some countries, for instance in Africa and in parts of Asia did not participate in ICILS. This entails that our knowledge regarding the assessment of digital literacy more globally is limited, and the unavailability of robust data in these contexts restricts our understanding surrounding these topics. Consequently, such issues might increase the digital divide with regard to access to technology and the development of students' and teachers' digital competence.

There are examples of tests and instruments that are being developed at national levels (e.g., in Australia, Norway and Hong Kong) in order to measure the digital skills and competences of students and teachers, but many of these are still in development (Erstad, 2008; Scherer et al., 2017; Tondeur et al., 2016). Reports from the ICILS 2013 and 2018 document the ways digital technologies are used in education in the participating countries, the competences of students and the self-reported attitudes and self-beliefs of the teachers (Fraillon et al., 2014, 2020). Moreover, these assessments have slightly changed across testing cycles. For instance, the 2018 ICILS included tasks for measuring computational thinking in addition to digital literacy, and both will also be assessed in the 2023 cycle. This ongoing transformation, along with developments in the processes of both collecting and processing assessment data, demonstrates that the assessment of 21st century skills is complex and changing as our knowledge regarding the constructs at play evolves and new technology and procedures for dealing with such assessment and data are developed.

National 21st century skills assessment—projects

To illustrate that some of the international cases mentioned above are also being emphasized and investigated through new initiatives and projects nationally, we will briefly present three examples of ongoing projects within our own research communities that target 21st century skills and new assessment initiatives.

Example 1: “Teaching and transfer effects of 21st century skills—collaborative problem solving in digital environments” (TEACH21st)

The TEACH21st project¹ is aimed at developing teaching material and practices for increasing upper secondary students’ “collaborative problem-solving competencies” (ColPS) and investigating whether the training of ColPS skills affects competences in both the domains under instruction as well as in other domains through transfer effects. This is a 4-year project (2019–2023) funded by the Norwegian Research Council. The project is designed to narrow the gap between research and practice by involving key stakeholders, focusing on the relevant curricular goals and including a classroom and student perspective (Siddiq et al., 2020). The initial phase (see Fig. 3) of the project focuses on the development and piloting of materials and practices to teach ColPS. To achieve this goal, a teacher design team (TDT) approach (Tondeur et al., 2016) has been employed. The TDTs consist of teacher educators, in-service teachers and student teachers who design educational material integrating ColPS with subject teaching. By involving different stakeholders in the design process, the implementation of new curricula in educational practice and its gradual application to classrooms is more likely to succeed (Wang and Hannafin, 2005). The TDTs are led by teacher educators from three different teacher-training institutions and are supported by the international project team. Throughout the developmental phase of the project, indicators of ecological and content validity are being developed to ensure that the teaching program is feasible, relevant for upper secondary curricula and classrooms, easy to implement and inclusive of the core elements of ColPS. In the second phase of the project (Fig. 3), one of the ColPS teaching programs developed by a TDT will be used in a randomized controlled trial (RCT). The project has just entered the second phase (fall 2021), and its focus is on preparing the intervention (i.e., one of the teaching materials developed in this project) and identifying, selecting, revising and developing the relevant assessments for the pre- and post-tests.

Example 2: “Educational assessments of the 21st century: measuring and understanding students’ adaptability in complex problem solving situations” (ADAPT21)

The ADAPT21² project aims at assessing students’ adaptability in complex problem-solving situations, building on the need for more knowledge about this as a critical 21st century competence. Adaptability is understood as the ability to adjust one’s thinking, behavior, and affect to novelty and change. Given the lack of performance-based assessments of such skills (Scherer, 2015), the project aims at developing such assessments by building on so-called “minimal complex systems”—computer-based assessments that capture the core cognitive processes involved in complex problem solving. These systems will present students with complex problems that are subject to novelty and change. Data from around 1000 students has been collected, including the logfiles of each subject, which do not only record the students’ responses for each task but also how they went about finding the solutions. The project is entering its last phase (fall 2021), focusing on data analysis and dissemination.

Example 3: “Modeling collaborative problem-solving data: new approaches for individual and team level inferences”

The project titled “Modeling collaborative problem-solving data: new approaches for individual and team level inferences”³ aims at developing a set of psychometric and statistical modeling approaches to the hierarchical nature of ColPS tasks. This is a collaborative project between two assessment units—the Centre for Educational Measurement at the University of Oslo (CEMO), Norway and the BEAR Center at UC Berkeley, USA—and is led by assistant professor Perman Gochyyev. This project builds on a background of increased focus on students’ collaborative problem-solving skills, and it gathers both individual and group-level datasets. The complexity of ColPS, along with the shortage of methods for processing and analyzing such data, underpins the focus of this project. For instance, in order to handle data from ColPS tasks properly, one needs to account for (1) the clustering of individuals within

Fig. 3 Design of the TEACH21st project.

¹<https://teach21st.usn.no/>.

²<https://www.uv.uio.no/ceмо/english/research/projects/adapt21/>.

teams, where individuals (i.e., students) are level-1 units and teams are level-2 units of analysis and (2) scoring items at different levels. One challenge lies in disaggregating individuals' cognitive (e.g., science) or noncognitive (e.g., perspective taking) skills under circumstances wherein their performance partially depends on their group's performance. Also, challenging is the extraction of cognitive and noncognitive skills at the group level after teasing out individual performances. Given that most ColPS designs require an elaborate approach to modeling the measurement data arising from their hierarchical structures, there are no readily available methods for researchers in this field. In particular, there is a need for testing cross-level differential item functioning (DIF) in the item parameters—that is, to what extent item difficulties and discriminations vary between teams. This project was initialized in 2020 but delayed because of the Covid-19 pandemic. The project is thus still running, and its results will be disseminated over time.

The transformative aspects of assessment in the 21st century

We end this chapter by raising some general reflections on the opportunities and possible pitfalls in understanding how we can and cannot assess 21st century skills, along with some future directions for this field of research.

Knowing that assessment is one of the most powerful determinants of practice in the classroom (Griffin et al., 2012, p. vi) and that it must be developed in order to “improve learning and support systemic education reform” (Kozma, 2009, p. 13), the extent to which our present educational systems manage to facilitate the development of 21st century skills curricula and assessment remains in question. However, as described earlier in this chapter, the attention given to the assessment of 21st century skills is rather superficial in both the leading international policy initiatives and national curricula. Along these lines, Scheuerman and Björnsson (2009) point out in their report focusing on new approaches to skills assessment that “existing models of assessment typically fail to measure the skills, knowledge, attitudes and characteristics of self-directed and collaborative learning that are increasingly important for our global economy and fast changing world. New assessments are required that measure these” (2009, p. 13).

The transformative potential of digital technologies for assessment was also raised by the Assessment and Teaching of 21st Century Skills project. These potentials are illustrated in Fig. 4 (Binkley et al., 2012, p. 27).

Fig. 4 provides a representation of the contrast between two key aspects of change and transformation as defined by this project—the business efficiency gains versus the educational transformation gains. The lower-left quadrant represents traditional assessments, which 10 years ago were typically paper-based but are now more often computer-based. Many school- and higher education-based assessments are of this type. Moving from the lower-left to the lower-right quadrant represents a migratory strategy by which paper-based assessments are shifted to a screen-based environment, which we see more examples of now. Delivery is more efficient, but the assessments are qualitatively unchanged. In contrast, moving to the upper-right quadrant is a transformational strategy in which technology is used to support innovative assessment designed to influence innovation in curriculum design and learning. The aim for the projects presented in this chapter is to reach this transformative stage combining innovative and technology-rich assessment. However, this has not reached a systemic transformation in any countries so far.

Most research on the use of digital technologies for assessment has dealt with its improvement of assessing traditional skills—improvement in the sense that such technologies have the potential for the large-scale delivery of tests and scoring procedures, easily providing the learner accessible feedback on their performance (Scheuerman and Björnsson, 2009; Siarova et al., 2017).

What concluding remarks can we draw based on the presentation in this chapter? We have argued that we need to understand how 21st century skills are defined and the key frameworks that contextualize these developments internationally, as well as how

Fig. 4 The dimensions of computer-based assessment innovations (Binkley et al., 2012, p. 27).

they are implemented at the national level. We believe there are several pitfalls that can move us in the wrong direction, especially if we create unfounded expectations for the ways digital technologies will change assessment systems by themselves or else fail to develop substantial research insights into how we can operationalize and measure not only “easy-to-measure” areas but also diverse 21st century skills. There is also a challenge of representation from historically underrepresented countries in large-scale assessment initiatives (Anjum et al. this Encyclopeida).

However, as we have emphasized in this text, there are several interesting initiatives in the making, internationally and nationally, that document the possibilities that exist in assessing 21st century skills. Over the last decade, and especially in the last couple of years, several examples of projects and initiatives have emerged that take advantage of developments in digital technologies and produce better understandings of complex skill-sets, using them to create items and instruments better suited to assessments and to building a knowledge base for future developments. A key possibility is also provided by recent curriculum developments in several countries around the world, highlighting the instruction of 21st century skills and key competences for the future as important dimensions of how education systems must now proceed in order to tackle future challenges in our societies, forwarding the skills and competences needed by young people growing up today.

As stated above, issues surrounding assessing and defining 21st century skills are part of a much broader discussion about systemic change in our education systems and models for that change. Assessment is a key element in any discussion about educational change, as well as a premise for the integration of teaching and learning 21st century skills in the classroom. If we do not further develop our assessment systems, it will be hard to accomplish any change in education at a systemic level. That is why the growing interest in and orientation toward 21st century skills have issued some directions for fundamental changes in which assessment is a key component.

In order to move in the direction argued for above, we believe there is a great need for more interdisciplinary approaches and projects. In order to develop good and sustainable tests and measurement instruments, we need to combine insights from fields such as psychology, technology, education, assessment/psychometrics and entrepreneurship/innovation. There is also a need to develop international large-scale projects targeting the assessment of 21st century skills in order to further collect experiences and insights in this field. There is a danger that many projects may stay as national initiatives or rely on a concentration of just a few skills that are defined as easier to measure. We need to produce approaches that better combine teaching and assessment that can support the learning processes of all students, a change already indicated by new curriculum developments. There are also opportunities for teachers and researchers to better collect and analyze the data that is now created by the digital footprints of students, and these areas will probably develop in a more robust and substantial way than we have seen until now in the years to come.

In our globalized world, immigration and temporarily movement between countries is an ever-growing phenomenon and an essential part of our society. Movement between countries happens for different reasons and with different prospects (IOM, 2019). While education is the driving factor usually for students in the tertiary sector, it can be assumed that immigrants also consider future prospects of their children including educational opportunities as being of major importance. In the OECD countries, the percentage of students with an immigrant background, or whose parents emigrated from another country, is continuously rising (OECD, 2019a).

Education systems are facilitators in the process of integration for all students. As societies are becoming more heterogeneous, education needs to adapt when catering to students from all over the world. Moreover, increasing global mobility has been here for several decades, which leads to a growing proportion of immigrant's children and their grandchildren in all nations (Sweetman and Ours, 2015). While immigration is an obvious part of all societies, inclusion of students with an immigration background still seems to be a challenge for many education systems. Indicators of system monitoring show significant differences in educational outcomes when comparing native and immigrant students. These differences also impact the prospects of the adult population (OECD, 2019a).

Consequently, education systems must face the fact that dealing with a heterogeneous student body might not come by itself, or as a byproduct of a heterogeneous society.

This chapter focusses on latest findings regarding immigrant students' educational attainment and the growing importance of immigration as a topic in education policy, as emerged from the data and results of International Large Scale Assessment (ILSA). It informs about different definitions of immigrant students, summarizes major findings regarding education outcomes, and highlights possible mechanisms on the system and school level for promoting inclusive education systems and school settings.

Immigrant students in ILSA—indicators for policy and practice

Indicators addressing the educational attainment of different groups in a society are relevant when it comes to evaluating the quality aspects of an education system. Policy makers need to be informed about progress and developments toward specific goals, for example the UN sustainable development goals (United Nations, 2015). These goals state—among others—equality for all and quality in education. Countries acknowledging these goals are asked to state their progress, using comparable indicators to track their success. Indicators included in ILSA can be used to monitor progress toward these goals (IEA and UNESCO, 2020; Kaplan and Lee, 2018). Moreover, ILSA inform about the equality of educational opportunities and allow estimating the effects of the family background, including the immigrant status, on educational outcomes (Hanushek and Wössmann, 2011).

Education policy needs to be aware of the development of these indicators as schooling in the host country is obviously the key factor for educational success, which in turn is a prerequisite for labor market prospects. When it comes to evidence informed policy focusing on immigrant students, ILSA are a state-of-the-art source for data on educational outcomes of different student populations. They offer indicators on change over time and provide an insight into teaching and learning contexts which can be related to specific countries policies, including immigration policies (for an overview on potential policies see de la Rica et al., 2015).

While workforce migration and student population in tertiary education is often in the focus of national monitoring, key indicators and policy regulations, little is known about immigrant students on the primary or secondary level (K-12) on a global scale. The diversity of datasets available—and in some cases the lack thereof—might pose a challenge for policy makers if they want to determine the needs for adapting primary and secondary education to a growing and more heterogeneous society. With the OECDs migration outlook, the EUs approach on monitoring, and the Global Education Monitor, different sources of information have been merged and provide a comprehensive overview (EU, 2017; Unesco, 2018; OECD, 2020a).

Many parts of these reports are based on data from ILSA. Large scale assessments as valid instruments for monitoring students' achievement in different competence areas and in education systems around the world regularly include different indicators of the student's heritage. The relevance of assessing indicators of immigration background arises from empirical findings which highlight

significant gaps between immigrant and non-immigrant students when it comes to educational outcomes and performance (see below).

The most prominent ILSA which continuously provide indicators of achievement, context factors and immigration status of students are the Trends in International Mathematics and Science Study (TIMSS), the Program for International Student Assessment (PISA), and the Program for International Reading Literacy (PIRLS). TIMSS and PIRLS use grade-based samples of fourth and eighth grade students while PISA targets 15-year-old students. PISA assesses competencies in reading, mathematics, and science as well as in innovative fields like problem-solving or global competence. PIRLS measures reading competencies of primary school children and TIMSS focusses on skills in mathematics and science in the fourth and eighth grade. Both PIRLS and TIMSS use a curriculum-based approach in their competence frameworks, while PISA focusses on a broader concept of literacy (for an overview of differences and similarities see [Klieme, 2016](#)). In addition to the tests assessing cognitive skills, all studies use questionnaires for students to capture attitudes and context factors of learning which are related to the educational outcomes ([Jude, 2016](#); [Jude and Kuger, 2018](#)).

The results of ILSA regularly raise awareness for the situation of immigrant students and the need for respective education policies. At present, ILSA offer a rich system of indicators which can be used to monitor the progress countries make in integrating immigrant students. Moreover, these studies allow to analyze context factors on different levels of the education system which support or hinder the success of immigrant students. These context factors include the input into the education system regarding resources as well as the processes on school level. Regular monitoring of respective indicators can point education policy to challenges countries will need to face in the future ([OECD, 2020d](#)). For many countries, studies like TIMSS or PISA were the first ever datasets to exist that included indicators of students heritage, showing in many cases a significant gap between native and immigrant students regarding mean values of educational outcomes. The results differ between countries and groups of immigrants within countries, still the overall discrepancies are of major importance. Interestingly though, gaps are not necessarily present in non-cognitive indicators and attitudes.

It needs to be stated that immigrant students are by no means a homogenous group. Consequently, different indicators need to be considered when describing challenges and prospects of immigrant students and defining an immigrant status.

Definition of immigrant status

The immigration status of students participating in ILSA is typically assessed with a questionnaire given to all the students taking part in the assessment. These questionnaires ask the students where they themselves and their parents were born. The indicators register if the students were born in the country where they currently attend school (host country), or in another country. In some studies, questionnaires for parents of the participating students assessing their heritage are added to the database.

Using these indicators, the migration status of students can be classified into different categories: students born in the country where they currently attend schooling and students born abroad in relation to the country where they currently attend schooling. Students born abroad are also called first-generation immigrants. In addition, students born in the host country can still be attributed an immigration background if one or both of their parents were born abroad. They are called second-generation immigrants. Some ILSA add questions asking about the specific country of origin which can be used to track migration movements as well as differences in educational achievement which might be related to specific heritage groups ([OECD, 2019b](#)).

As immigration movements change over time, so does the share of first and second generation students within a country. In countries with a long history of immigration, more students of a second, or even third generation with immigration background will attend schools and universities, whereas in countries where immigration is a relatively new phenomenon, the students themselves will have migrated with their parents. In recent years, new waves of immigration have started, bringing with them once again first-generation students and their families ([OECD, 2020a](#)). As it can be assumed that the educational needs of these different groups vary, tracking the development of these indicators is crucial when education systems want to adapt their resources.

Another indicator of immigration background assessed with questionnaires in ILSA is the language spoken in the home of the students. Questions in the questionnaire ask the students if the language they speak in their family most of the time if the language of the instruction in the country or another language. This indicator can be used for in-depth analysis in addition to the country of birth, as many immigrants speak their heritage language in the families and are thus often multi-lingual, whereas education in most countries is mono-lingual. As language competence is the key factor when it comes to educational success, and most subject areas even require their own technical language, education systems need to enable support structures for students whose native language is not the language of instruction in the country they are currently living in ([Li, 2013](#); [Hoff, 2018](#)).

Some ILSA assess the age in which the students moved to the country where they currently attend schooling. This information can help identify areas of action for policy which can differ depending on the respective institutions on different levels of the education systems, for example kindergarten and pre-school, primary school, and secondary education. Moreover, tracking the success of student groups which migrated at different time points in their educational career can give insights where integration in the host country works well ([OECD, 2012a](#)). When looking at factors influencing immigrant students' performance in ILSA compared to those of non-immigrants, the age of arrival in the host country indeed needs to be considered. On average, performance is correlated with the age of arrival: The later students arrive in the host country, the lower they perform in assessments. However, the effect of arrival age differs between countries, as covariates like the language barrier, any differences between the school-systems like tracking or immersion practices, as well as differences in educational standards need to be taken into account ([OECD, 2012a](#)).

ILSA data, though it is currently the most prominent indicator system in this area, only provides limited information on the sample of immigrant students. Even though these studies comprise a representative sample of students on the country level for each participating nation, the prerequisite for being tested is that students have at least received one year of instruction in the language of assessment in the host country (OECD, 2019b). Accordingly, students who just arrived in the country and do not have sufficient language competencies are not represented in the samples. It can thus be assumed that effects of immigration might be underestimated when relying solely on ILSA data.

Overall, the immigrant population is becoming more and more diverse, i.e., the number of different heritage countries is rising with the increasing phenomenon of refugee children attending school in various countries (OECD, 2015a; Dryden-Peterson, 2015). Thus it could be argued that immigrant status should not necessarily be a defining attribute for those students which were born in the country, i.e., second-generation immigrants. This would mean that they inherit an attribute which does not really belong to them but has been carried over from parents, sometimes even grandparents. Still the phenomenon exists that we can see differences when it comes to educational outcomes of immigrant students even in the second generation, and in many cases also when only one parent was born abroad.

Several studies have investigated and compared findings from ILSA regarding the performance gaps. As different surveys vary in their definition and assessment of competencies and focus on different age groups, they can be used to analyze the overall phenomenon from different perspectives.

Educational outcomes of immigrant students

Ideally, education systems aim for fair opportunities for all students. Fair opportunities imply that educational outcome and success only depends on one's abilities and is not influenced by unjust distribution of resources or unequal possibilities. Thus, the challenge of system monitoring is to identify potential sources of these gaps and highlight the role of education policy and schools to overcome any systematic barriers which would lead to discrimination of specific groups of students. Students with an immigration history can be seen as a specific group of students despite their heterogeneity. Accordingly, system monitoring needs to analyze if differences in the educational success of native and immigrant students exist on a broad scale, and if this is due to systematic mechanisms in the education system.

The current discussion on the rise of immigrant students reflects contradictory findings when it comes to their educational outcome. While most studies strongly suggest that achievements of students with an immigration background on average are lower than those of the native students in the respective country, latest research points to considerable variation in these findings. The variations are reflected between the different host countries, between specific heritage countries, and also between school subjects and educational grade. Accordingly, even though performance gaps can be seen when looking at the average, they are not persistent across all conditions.

In most countries, it is the native students which on average perform best. First-generation immigrant students show lower performance and second-generation immigrant students are still outperformed by native students but show higher performance than their first-generation peers. It is important to note that these results only refer to the average across all students with an immigration background on a global scale. The gap is however not homogenous across countries, differs between specific subject areas and has been found to be related to different covariates (Andon et al., 2014). In some countries, the gap closes over time and in a few exceptions, immigrant students outperform the native ones (Alieva et al., 2018; OECD, 2016).

While significant differences in mean performance between native and immigrant students can be found in all ILSA, across countries and subjects, there is also a substantial variation to be noted. This leads to the conclusion that country specific policies could mediate the correlation (Andon et al., 2014). While immigrant students on average show lower outcomes compared to native students in mathematics and science (Hastedt, 2016), the variance of achievement is higher for students with an immigration background than among non-immigrant students (Schnepf, 2008; OECD, 2012a).

Performance can also be analyzed regarding percentiles, e.g., the share of immigrant students among the 25th and 75th percentile marking the group of low and high performers. For most but not all countries, immigrant students are over-represented among low achievers and under-represented among high achievers (OECD, 2012). On average in the OECD countries, the proportion of low performers among immigrant students is twice as high as among native students. The opposite is true for the highest competence levels: Here, the share of top-performing native students is almost twice as high as the proportion of their immigrant peers. This means that on average of all students with an immigration background, half of them do not reach basic levels of competence at the age of 15 (Schnepf, 2004; OECD, 2018).

An important aspect of educational prospects is the language immigrant students speak at home with their families. On average in the OECD countries, more than 60% of first generation immigrants and more than 1/3 of the second generation speak their heritage language at home which is different from the language of instruction in the host country (OECD, 2016). Regarding educational performance, the gap is significantly smaller between migrant and native students if the host-country language is spoken at home, still language proficiency seems to have a stronger impact on achievement in, for example, reading assessments than in the subject of mathematics (Schnepf, 2007; Cordero and Mateos, 2021).

The educational and economical level of the country of migration also reflects in the educational achievement in the host country—immigrant students arriving from a country with high educational achievements on average show a smaller achievement

gap in the host country (Gianellie and Rappalini, 2016). Thus the differences between the heritage and the host country need to be taken into account, as the heritage education system reflects in the students' performance also in the host country (Arikan et al., 2020).

While a substantial influence of the family background can be seen in educational performance for all students independent of their immigration background, this influence varies between countries (for an overview see Hanushek and Wössmann, 2011). Still the question remains if differential effects can be found when it comes to the impact of the family (Sirin, 2005; Kim et al., 2019). In their meta-analysis, Kim et al. (2020) show that parents proximal engagement, i.e., supporting students psychologically and getting involved in their learning, had stronger effects than the overall family background in immigrant families. Parents' knowledge about the host countries education system, their involvement and educational aspirations are also important when it comes to a successful integration (Hamish et al., 2016). It has been shown that the socio-economic status of students plays a crucial role when it comes to inclusion and can influence social cohesion in school and society. Consequently, current studies controlling for variation in the immigrant students background, find that performance gaps are reduced or even vanish when controlling the socio-economic background (Arikan et al., 2020).

When describing student populations with an immigration background, especially when comparing their educational achievements between countries, we need to be aware of determinative factors on the system level: Immigration policies between countries vary widely, along with policies in admitting refugees, which can reflect in the performance of immigrant students (OECD, 2015b). Consequently, cultures and socio-economic backgrounds of the immigrant population vary widely between and within countries, as do the education policies and school-level practices (Buchmann and Parrado, 2006). When looking at trend in performance gaps over time, while the differences between native and immigrant students still are significant, a decline in the overall performance gap can be seen in several countries (Riederer and Verwiebe, 2015). Thus, a closer look at policies on system and school level can reveal factors which support immigrant students' educational success.

Education policy and equality of opportunity

To guide education policy, it is importance to identify factors that support immigrant students. A topic that has widely been discussed in ILSA is the question of resilience and students well-being. Resilient students are those non-native students that are among the top-performers in the country of immigration, i.e., performing well against the odds (OECD, 2019a). When looking at the average achievement in reading across OCED countries, 17% of immigrant students can be found in the top-performing group, while in some countries, even 30% of immigrant student showed excellent reading scores (OECD, 2019a).

Factors supporting resilience can be found on the individual and the system level: Individual factors like self-efficacy, a growth-mindset and family support help when it comes to building resilience. Links between a growth-mindset and educational outcome are associated with a larger gain for immigrant students compared to their native peers (OECD, 2021).

On the school level, perceived teacher enthusiasm, co-operation in school and a more positive disciplinary climate in school help students to build resilience. When it comes to well-being, results show significant differences: High well-being at school is reported by fewer immigrant students than native students, and on the other hand, immigrant students are more likely to report feeling like an outsider at school (OECD, 2019a). When schools want to support students with heterogeneous backgrounds, their specific circumstances need to be recognized by offering support structures (Cordero and Mateos, 2021).

This leads to the interpretation that resilience and well-being are not effects of migration itself, but can be supported by schools and communities (OECD, 2018). There is no single factor which could be focused on when it comes to supporting educational participation and success of immigrant students. Rather, complex relationships between factors on the individual level (students and their families), the school level (teaching and learning), and the host countries society contribute to the overall educational outcomes. (Volante et al., 2019).

On the *system level*, most studies find effects of tracking and segregation policies on the achievement of immigrant students: Differentiation usually goes along with a larger gap depending on socio-economic background, which is in turn most often related to the immigration background (Bodovski et al., 2020). Tracking within the school system usually correlates negatively with equality of educational opportunities. It also might impact educational pathways of students: while on average, many studies show that immigrant students have higher educational expectation than their native peers, this difference is smaller in tracked systems. Bigger inequalities can be found in systems which implement early tracking, increasing inequalities in achievement between students with different family backgrounds (Contini and Cugnata, 2020; Dronkers et al., 2014). Moreover, the country of origin of the students seems to be of importance when selection mechanisms in highly tracked systems are in place (Alieva and Hildebrand, 2019).

However, latest studies point to the need for differentiation of effects when distinguishing between groups of immigrant students, for example taking into account the age of arrival in the host country and students language competence (Borgonovi and Ferrara, 2020), but also the age in which tracking occurs and the language spoken at home, still showing that late tracking enables equity and opportunities especially when students are less integrated. (Ruhose and Schwerdt, 2016).

On the *school level*, segregation is a strongly debated topic. In-school ability grouping seems to be related negatively to achievement with stronger effects for immigrant than non-immigrant student (He and Fischer, 2020). Cross-national studies show that school segregation and early tracking are usually related to lower equality of educational opportunities in the respective systems (Schütz et al., 2008). Stratification between schools is usually associated with a lower performance of immigrant students, especially when this is paired with segregation on the school level. Still, immigrant students can benefit from ability grouping within schools

(Teltemann and Schunk, 2016). Regarding the support of immigrant students, a high concentration of these students in disadvantaged schools is correlated with lower educational attainment (OECD, 2012b), one factor being that highly educated teachers usually can be found in high-SES schools (Rubinstein-Avila, 2016).

Schooling in all levels of education usually requires fundamental knowledge of the language of instruction. Hence, the success of immigrant students is related to their possibilities of acquiring *sufficient language proficiency* to follow instruction as well as their peers. Systematic policies to provide language learning opportunities for all immigrant student, independent of the age of arrival could support educational attainment, though language support especially in early childhood education is essential for later educational success (Entorf and Minoiu, 2005; Rubinstein-Avila, 2016). Policies which seems to positively influence inclusion can be found in countries which enforce education standards with centralized curricula and corresponding programs which reinforce language learning at all levels in the educational biography of students. This requires a skilled teacher workforce and adequate training for teachers in supporting a multi-lingual and heterogeneous student population (Christensen and Stanat, 2007).

Language competence can be seen as prerequisite for *participation and integration* in school and community, which reflects in a so-called sense of belonging. ILSA regularly show a correlation between sense of belonging and educational success. Data from the International Civic and Citizenship Education Study (ICCS) show that immigrant students report a lower sense of belonging on average (Ham et al., 2017), the PISA study finds that more than 40% of immigrant students report a weak sense of belonging, compared to 30% of native students (OECD, 2018). Still positive effects can be found when integration policies and anti-discrimination measures are in place which support social inclusion both for sense of belonging on the school level, but also on a national level when it comes to reducing the disparity between immigrant and non-immigrant students (Ham and Yang, 2020). Sense of belonging can be supported by integrating immigrant students in schools and fostering a positive relationship with teachers. Greater inclusion can be promoted by encouraging civic participation in school and the community (Rutkowski et al., 2014).

The background of students with refugee experience also needs to be considered, as requirements of these students differ significantly from other migration experiences. Disrupted or sporadic schooling in often traumatizing conditions influences not only performance, but also attitudes and educational expectations (Dryden-Peterson, 2015). Students' attitudes are related to the values shared in the society they are living in. The more inclusive and multicultural a society is, the higher the positive attitudes of students toward ethnic minorities (Kim and Byun, 2019).

Building an inclusive and welcoming setting for all students can be seen as a major challenge. *School climate and positive relationships* between students, their peers and teachers as well as civic engagement in schools and communities contribute to generalized trust, a comparable effect can be seen for ethnic diversity in the schools community (Choi and Lee, 2021). Openness and open classroom climate are positively associated with students civic and citizenship knowledge (Knowles and MacCafferty-Wright, 2015). Inclusive views regarding immigrants are correlated with the immigrant status of students; both the first- and the second-generation migrants are significantly more inclusive in their views on immigrants than native students. Mixed classrooms contribute positively to inclusive views of students as well as to positive attitudes regarding immigrants' rights (Janmaat, 2014; Isac et al., 2012).

For education policy as the target audience of ILSA results, it is important to learn not only about potential factors influencing differences between immigrant students and native students. Consequently, when discussing the rise of immigrant students in our education systems, the focus should not be only on cultural heritage, but rather on building society and schools that are able to support a growing heterogeneity amongst their student population in various aspects.

New challenges and outlook

Existing policies on system and school level were disrupted in the course of the pandemic that hit the education systems around the globe in early 2020. As a result, schools remained closed or switched to distance teaching for more than a school year (for an overview on national policies see OECD, 2020c). While it is yet to early to estimate the overall impact of this disruption on educational outcomes, current studies point to the fact that vulnerable students will face additional challenges: Students with an immigration background miss out on opportunities solely offered by schools, such as secure learning settings with the opportunity for immersion in the host countries language as well as participating in the society. Reducing these learning opportunities might impact not only educational outcome, but also the students' sense of belonging and educational aspiration. Moreover, learning support at home including technical resources is comparably limited and shows huge differences depending on the socio-economic and immigrant background (OECD, 2020b; Murat and Bonacici, 2020).

Education systems will need to face a challenge also in the years to come, when not only learning gaps, but also strains in regarding health and well-being in the student population will show their impact. Several ILSA have adapted their indicators to measure challenges and coping approaches of education systems and schools in dealing with the pandemic. The IES Responses to Educational Disruption Survey (REDS) will deliver insights on the country and school level policies which were implemented in dealing with disruption and distance learning. The PISA assessment in 2022 will be addressing differential effects of the pandemic on student learning and well-being across different education systems (Bertling et al., 2020).

Society and education systems will need to continue adapting to a changing and more heterogeneous population, and schools have a central function and responsibility not only to support students with an immigration background, but also to help develop intercultural skills in schools and society at large.

Immigration and worldwide movement of labor force are constant phenomenon in a globalized world. While some countries might be more affected than others, most countries will continue to be faced with challenges when it comes to adapting their education system to a more and more heterogeneous body of students in all levels of education. All stakeholders in education need to react to enable successful education for all students independent of their heritage.

As can be seen when analyzing ILSA data, the variation between students with an immigration background is high—variation refers to countries of origin, heritage language but also educational achievement. Differences in educational outcomes depend on heritage, countries of origin, language spoken at home but also on the education policies in the host countries. While in most countries immigrant students are outperformed by their native peers in standardized tests of achievement, they prosper in a limited number of countries. Moreover, immigrant students show higher competences when it comes to civic attitudes and intercultural aspects.

Meanwhile, when looking at the trend of ILSA data over the last 20 years, changes in the performance of immigrant student over time can be seen. In many countries, this can be attributed to education and social policies fostering integration. For some countries their overall average score point in ILSA improved solely because the educational outcomes of immigrant students increased, while those of the native students remained stable. There is a need for policies to regard immigrant students especially when it comes to teacher training and inclusion policies in schools. To overcome the specificity in the discussion of equity in education, monitoring should not only focus on minorities, but needs to broach the topic of inclusion for all independent of their heritage, without neglecting needs of groups of students which might face specific challenges. Education system which are truly global value and welcome heterogeneity in all aspects by adapting to the needs of all students to help them succeed.

Evaluation is the determination of something's quality, value, or importance. *Metaevaluation* is the evaluation of evaluation.

The cradle of metaevaluation was educational evaluation. Orata's (1940) article "Evaluating Evaluation" in the *Journal of Educational Research* introduced the evaluation field to the general function of formal metaevaluation. In that article, Orata assessed the state of educational and student evaluation and made evaluative claims about the merits of well-known studies, including Ralph Tyler's landmark Eight-Year Study (Smith and Tyler, 1942). Nearly 30 years later, in 1969, Michael Scriven, a preeminent evaluation theorist, coined the term *metaevaluation* in an *Educational Products Report* article about evaluating educational products. In defining metaevaluation, Scriven described both a theoretical function and a practical one. The theoretical function of metaevaluation "involves the methodological assessment of the role of evaluation." The practical function "is concerned with the evaluation of specific evaluative performances" (Scriven, 1969, p. 36).

As defined by Scriven, the theoretical and methodological roles of metaevaluation parallel the two meanings of *meta* as summarized by Thomas (1984, p. 18): (1) "knowledge about" or "analysis of" and (2) "encompassing multiple aspects of instances of the phenomenon under consideration." Stufflebeam (2001, p. 183) argued that metaevaluation (i.e., engaging in evaluation at these meta-levels) "is a professional obligation of evaluators." Scriven (2009, 2011) extended this professional imperative to claim metaevaluation is an ethical imperative. He argued that metaevaluation is the "conscience of evaluation" and that the survival of evaluation as a discipline depends on it.

Metaevaluation's theoretical function is realized through two streams of activity: evaluation theorizing and research on evaluation.

[☆]Change History: May 2021. L. Wingate, Z. Tilton, and M. Harnar updated the text of the entire article.

Evaluation theorizing is broadly viewed as any writing on evaluation (Shadish, 1998). More specifically, it involves generating and refining “explanations of underlying fundamental issues such as the nature of evaluation purpose, valuing, evidence, use and so on” (Smith, 2010, p. 384). Various frameworks for conceptualizing the use and influence of evaluation and the numerous distinct approaches to evaluation fall under the umbrella of evaluation theorizing.

Research on evaluation refers to “any purposeful, systematic, empirical inquiry intended to test existing knowledge, contribute to existing knowledge, or generate new knowledge related to [evaluation]” (Coryn et al., 2016, p. 161). Such studies serve the theoretical function of metaevaluation by producing insights about the use and influence of evaluation within organizations and within society.

Scriven’s second dimension of metaevaluation—the evaluation of evaluation performances—is currently the dominant connotation of metaevaluation. This practice involves systemically examining specific evaluations to determine their quality.

This article focuses on practical metaevaluation as applied to program evaluations, specifically educational program evaluations. It introduces and explains metaevaluation’s purposes, metaevaluation questions and criteria, and methods for conducting metaevaluations. A few practice examples illustrate how these key concepts manifest in real-world metaevaluations of educational programs.

Metaevaluation purposes

Metaevaluations are conducted for the same reasons that evaluations are conducted. The chief purposes of evaluations are (1) to identify ways to improve an effort while it is underway or (2) to determine an effort’s overall quality and effectiveness to inform decisions about whether it should be continued, expanded, reduced, or discontinued. Additionally, evaluations may be conducted (3) to generate knowledge about the type of effort being examined, for example, to gain insights about program implementation. Respectively, these purposes are *formative*, *summative*, and *ascriptive*.

In primary evaluation, the effort in question is typically a coordinated set of activities intended to improve some aspect of the human condition or organizational functioning (i.e., a program). In metaevaluation, an evaluation itself is the focus. However, the primary purposes are the same, whether the focus is a program or its evaluation.

Formative metaevaluation

Formative metaevaluation occurs while an evaluation is underway. Its purpose is to identify opportunities to improve the primary evaluation. If no improvement is needed, then the formative metaevaluation serves as a confirmation of the evaluation’s quality. Such confirmations may enhance stakeholders’ confidence in the evaluation process and subsequent results.

In a formative metaevaluation, draft evaluation materials, such as evaluation plans, instruments, protocols, and reports, may be subject to review and feedback by a metaevaluator prior to finalization, implementation, or dissemination. Less tangible aspects of a primary evaluation may also be assessed in formative metaevaluation; for example, a metaevaluation may assess data collection and analysis procedures; evaluators’ competence; and the evaluation’s responsiveness to stakeholders’ information needs.

The most significant potential benefit of formative metaevaluation is that it can reveal deficiencies in the primary evaluation at a point in time when they can be remedied. In this way, a formative metaevaluation could prevent the primary evaluator from making serious errors such as overlooking critical stakeholder groups, reaching faulty conclusions due to poor data quality, or failing to demonstrate cultural competence. Some scholars have argued that the mere presence of a metaevaluator while an evaluation is underway reduces bias and increases rigor (Fitzpatrick et al., 2004; Scriven, 1975). That is, even evaluators are susceptible to the Hawthorne effect (Landsberger, 1958), a form of reactivity that takes place when those being evaluated perform better simply because they are aware they are being observed.

By surfacing potential problems early, a formative evaluation can increase a primary evaluation’s quality. It can also enhance an evaluation’s cost-effectiveness by ensuring resources are used effectively (Yarborough et al., 2011; Stufflebeam and Coryn, 2014).

Summative metaevaluation

A summative metaevaluation assesses the quality of a completed evaluation. It involves judging the appropriateness of an evaluation’s processes, the validity of its conclusions, or the usefulness and influence of the evaluation as a whole. For example, a summative metaevaluation may examine the extent to which evaluators delivered what was promised, used resources efficiently, and acted ethically. In addition to informing such accountability issues, a summative metaevaluation may serve a verification purpose. That is, a summative evaluation might confirm or refute an evaluation’s conclusions (and recommendations, if present). Summative metaevaluation that checks the veracity of findings and appropriateness of methods is especially important when the stakes are high and important decisions hinge on the evaluation’s results (Patton, 2008; Stufflebeam and Coryn, 2014), as was the case with the summative metaevaluation of the Paris Declaration on Aid Effectiveness (OECD, 2005). That metaevaluation was conducted concurrently with the evaluation of the Paris Declaration, in which the primary evaluation spanned 4 years and involved 50 studies across 22 partner countries with reviews by 18 donor agencies (Patton and Gornick, 2011).

When a summative metaevaluation validates a primary evaluation, it adds credibility to the evaluation. It may enhance the primary evaluation stakeholders’ confidence in using the evaluation findings to inform decisions to expand, modify, or cancel

programs. When a summative metaevaluation finds severe flaws in a primary evaluation, it can help prevent decision-makers from taking actions based on faulty information. Evaluation consumers, clients, and practitioners can use summative metaevaluations in a formative manner by applying what they learned in the summative metaevaluation to improve future evaluations.

Ascriptive metaevaluation

Metaevaluation is ascriptive when it is done for the sake of generating knowledge about evaluation (Scriven, 2011). This type of metaevaluation is not done to provide instrumental decision support as are formative and summative metaevaluations. Instead, ascriptive metaevaluation is done to gain insights about the state of evaluation, the impact or effectiveness of certain evaluation practices, and other issues whose study contributes to advancing evaluation as a professional practice and form of inquiry. Ascriptive metaevaluations are often conducted by graduate students for their theses as a means of conducting research on evaluation (Henry and Mark, 2003; Mark, 2008). Here, Scriven's conceptualization of the theoretical and practical functions of metaevaluations converge. That is, ascriptive metaevaluation serves the practical purpose of determining the quality of a specific evaluative performance, and it does so in the service of advancing knowledge about evaluation itself as a professional practice or form of inquiry—i.e., it is also an example of the theoretical function of metaevaluation.

Distinguishing metaevaluation from synthesis studies

Metaevaluation is often confused with meta-analysis, which is a process for synthesizing quantitative results from multiple studies to determine an overall effect for the type of intervention being studied. Qualitative analogs to meta-analysis include systematic reviews and qualitative reviews. Whether qualitative or quantitative, such synthesis studies involve finding, screening, combining, and extracting data from primary research and evaluation studies. The screening process involves assessing the primary studies to determine whether they meet established thresholds for quality or rigor for inclusion in the synthesis. Thus, there is a meta-evaluative step in syntheses of evaluation studies. However, meta-analysis and other types of synthesis studies are not the same as metaevaluation (although some noted organizations and scholarly publications conflate the concepts, adding to the confusion).

We join other evaluation scholars who distinguish metaevaluation from synthesis studies such as meta-analyses and systematic reviews (Scriven, 2009; Schwandt, 2015; Stufflebeam and Zhang, 2017; Mertens and Wilson, 2019). In short, if a study's purpose is to judge the quality of evaluations, it is a metaevaluation. If its purpose is to reach conclusions about the programs or other initiatives that were evaluated, it is not a metaevaluation.

Metaevaluation questions and criteria

Metaevaluation questions define the scope of the inquiry. Criteria provide the basis for reaching judgments in relation to those questions. Both questions and criteria stem from evaluators' and associated stakeholders' values and assumptions about how the object of an evaluation should perform and what it should achieve. Therefore, questions and criteria are inextricably linked and must be considered in tandem.

Questions

As in a primary evaluation, the focal questions in a metaevaluation are determined based on the study's purpose and intended uses. However, various evaluation scholars have recommended sets of general metaevaluative questions. These general questions can be used to determine more specific questions for a given metaevaluation.

Regardless of the specific questions, metaevaluations by definition focus on questions about an evaluation's quality, value, or importance (Evaluation scholars tend to use the terms *merit*, *worth*, and *significance* as synonyms for those more commonplace terms).

Stufflebeam and Coryn (2014, pp. 653–654) said the fundamental question about an evaluation's merit is "how well it meets the requirements of a sound evaluation." They said the critical issue regarding an evaluation's worth is "its sufficiency in meeting the audience's evaluative information needs."

Patton (2008, p. 570) suggested these basic metaevaluation questions that focus on evaluation processes: "To what extent was the [evaluation] implemented as designed? What adaptations occurred during implementation and what are the implications of those adaptations for intended and unintended outcomes?"

The Joint Committee on Standards for Educational Evaluation (Yarbrough et al., 2011, p. 241) identified the following questions among those that a metaevaluation might address:

- Were the findings for the program evaluation clear?
- Were the design and implementation of the design appropriate for the study?
- Were the conclusions justified by the data?
- Were the results adequately disseminated? Were they used?

Stakeholders involved in a metaevaluation can use these general questions as prompts to generate more specific questions that reflect their values, concerns, and information needs.

Criteria

Commenting on the salience of criteria in any evaluation context, [Patton \(2020, p. 581\)](#) explained,

It's all about criteria. Criteria are the basis for evaluative judgment. Determining that something is good or bad, successful or unsuccessful, works or doesn't work, and so forth and so on requires criteria.

Since the point of a metaevaluation is to reach conclusions about evaluation quality, it is essential to identify what quality means in a given evaluation situation. The selected criteria should make sense within the geographic and cultural context in which the primary evaluation was conducted, as well as with regard to its philosophical or theoretical underpinnings.

Various voluntary organizations for professional evaluation (VOPEs) and multilateral organizations have developed criteria that define evaluation quality for their contexts. [Table 1](#) lists 11 prominent evaluation quality frameworks. (Websites for these frameworks are listed under Relevant Websites at the end of this article.)

These frameworks define criteria for high-quality evaluation in their respective contexts. Evaluators can use them to guide their practice. Familiarity with them helps evaluation commissioners and other stakeholders to be more informed evaluation consumers. In the context of metaevaluation, these frameworks provide the foundational criteria for judging evaluation quality.

Many organizations that have authored evaluation quality frameworks have also put forth companion documents that define professional competencies for evaluators working in their contexts, as well as separate guidelines for ethical practice. Strictly speaking, these are not criteria for judging the quality of evaluations. Instead, they define how professional evaluators should conduct themselves. While the competence of evaluators figures into evaluation quality, a competent evaluator can certainly conduct a poor evaluation.

Grounding metaevaluation in codified, widely accepted criteria for evaluation quality promotes consistency and professionalism in evaluation practice. Evaluators do not need special certification or licensure processes to practice evaluation or call themselves evaluators. As rare exceptions, Japan and Canada have voluntary credentialing systems ([Kuji-Shikatani and Imata, 2018](#); [Canadian Evaluation Society, 2014](#)). In its lack of regulation, the evaluation profession contrasts sharply with the fields of accounting, medicine, law, and psychology, and the construction trades, in which regulatory practices are well-established. In the absence of regulation, it is incumbent on evaluation practitioners, clients, managers, and consumers to educate themselves about what constitutes evaluation quality. The use of established evaluation quality frameworks to both guide and assess evaluation practice helps advance a shared expectation for professional evaluation practice.

Next, we review a few examples of evaluation quality frameworks to highlight criteria that have been developed for use in different regions and sectors.

Program evaluation standards—joint committee on standards for educational evaluation

The Program Evaluation Standards were developed by the Joint Committee on Standards for Educational Evaluation ([Yarbrough et al., 2011](#)). The Joint Committee formed in 1975 as a coalition of several US and Canadian organizations with that each had a stake

Table 1 Region- and organization-specific evaluation quality frameworks.

<i>Authoring organization</i>	<i>Evaluation quality framework</i>
African Evaluation Association	African Evaluation Guidelines
Aotearoa New Zealand Evaluation Association	Evaluation Standards
Department of Performance Monitoring and Evaluation, Presidency of the Republic of South Africa	Standards for Evaluation in Government
German Evaluation Society	Standards for Evaluation
Joint Committee on Standards for Educational Evaluation	Program Evaluation Standards
Latin American and Caribbean Network of Monitoring, Evaluation and Systematization	Evaluation standards for Latin american and the Caribbean
Organization for Economic Co-operation and Development, Development Assistance Committee	Quality Standards for Development Evaluation
Swiss Evaluation Society	Evaluation Standards
Uganda Evaluation Association	Uganda Evaluation Standards
United Nations Evaluation Group	Norms and Standards for Evaluation
United States Government Accountability Office	Government Auditing Standards (Specifically for Performance Audits)

in educational evaluation. The Committee published its first set of standards for program evaluation in 1981 and subsequent editions in 1994 and 2011.

Several distinguished evaluation scholars and practitioners have identified the Program Evaluation Standards as one of the most important sources of criteria for assessing evaluation quality in the US context (Fitzpatrick et al., 2022; Patton, 2008; Schwandt, 2015; Scriven, 2013; Stufflebeam and Coryn, 2014). They include 30 distinct standards that define evaluation quality in five domains: Utility, Feasibility, Propriety, Accuracy, and Accountability.

The *Utility* standards explain that evaluation should be useful and valuable to stakeholders. The *Feasibility* standards call for evaluations to be conducted efficiently and be responsive to their cultural and political contexts. The *Propriety* standards address issues such as consent, confidentiality, ethics, and social justice. The *Accuracy* standards call for evaluations to be methodologically sound, transparent, and culturally appropriate. Finally, the *Evaluation Accountability* standards explain that evaluators should fully document and evaluate (i.e., metaevaluate) their work.

The individual Program Evaluation Standards are broad statements; for example, the accuracy standard on communication and reporting states, “Evaluation communications should have adequate scope and guard against misconceptions, biases, distortions, and errors.” Each standard is elaborated with a rationale, guidance for meeting the standards, a description of hazards evaluators may encounter related to the standard, and a scenario to help readers understand how the standard manifests in practice.

The Joint Committee’s Program Evaluation Standards, developed for use in the US and Canada, were the basis for evaluation standards defined by the following VOPEs:

- African Evaluation Association
- German Evaluation Society
- Latin American and Caribbean Network for Evaluation
- South African Department of Performance Monitoring and Evaluation
- Ugandan Evaluation Association

African evaluation guidelines—African Evaluation Association (AfrEA)

AfrEA’s framework is made up of 22 principles that define evaluation quality in the African context (AfrEA, 2007, 2020; Nairobi M&E Network et al., 2002). The 2002 and 2007 versions of AfrEA’s standards were closely aligned with the Joint Committee’s Program Evaluation Standards. In contrast, the latest iteration of these principles, published in draft form in 2020, reflects AfrEA’s Made in Africa initiative to develop and promote a “uniquely African approach to evaluation.”

The *Powerful for Africans* principles emphasize empowerment, learning, and capacity development. The *Technically Robust* principles address rigor, transparency, efficiency, cultural responsiveness, and other factors that affect an evaluation’s technical quality and credibility. The *Ethically Sound* principles call for protecting and respecting the people involved in an evaluation and attending to equity, diversity, and inclusion. Principles under the heading *Africa Centric, Yet Open* are about prioritizing African values and methods while engaging with indigenous communities and, more broadly, the global south. The *Connected With The World* principles are about acknowledging and fostering interconnectedness across communities and with nature, calling for evaluations to contribute to transformative change.

Evaluation standards—Aotearoa New Zealand Evaluation Association (ANZEA)

ANZEA formed in 2006 to represent the needs and interests of evaluators working in New Zealand (Aotearoa is the Māori name for New Zealand). The ANZEA standards are grounded in the Treaty of Waitangi, New Zealand’s founding document, and reflect the values of New Zealand’s indigenous populations (ANZEA, 2015). There are 20 ANZEA evaluation standards that define four overarching evaluation principles.

The standards for *Respectful, Meaningful Relationships* call for nurturing positive relationships among everyone involved in an evaluation in mutually beneficial and culturally appropriate ways. The *Ethic of Care* standards convey the importance of kindness, respect, humanity, reciprocity, cultural sensitivity, safety, inclusion, privacy, and confidentiality in evaluation. The standards for *Responsive Methodologies and Trustworthy Results* call for evaluators to use methods that are culturally and technically appropriate and ensure findings and conclusions are meaningful and credible. The *Competence and Usefulness* standards explain that both evaluators and evaluation commissioners must be professionally, contextually, and culturally competent and that evaluations should generate useful information.

Quality standards for development evaluation—Organization for Economic Co-operation and Development (OECD) Development Assistance Committee (DAC)

OECD includes 31 member countries that make development investments worldwide. The OECD’s *Quality Standards for Development Evaluation* (2010) include 27 standards in four categories. The standards apply to evaluations of international aid initiatives and development assistance, including humanitarianism, sustainable development, conflict response, and peacebuilding. They are intended for evaluation commissioners and practitioners within the OECD network, including those from bilateral donors and multilateral development agencies and especially those who use the OECD-DAC criteria in primary evaluations.

The OECD’s evaluation quality standards under the heading of *Overarching Considerations* include high-level statements about the nature of development evaluation, ethics, capacity development, and other general topics. The *Purpose, Planning, and Design* standards address a diverse set of topics related to defining an evaluation’s purpose and focus, selecting criteria and methods, and

management considerations. The standards related to *Implementation and Reporting* cover a range of issues related to people, resources, contexts, execution of the evaluation's design, and the evaluation's products. Finally, the *Follow-Up, Use, and Learning* standards underscore the importance of taking action after an evaluation to enhance its use and influence.

Norms and standards for evaluation in the United Nations systems—United Nations Evaluation Group (UNEG)

The *Norms and Standards for Evaluations in the United Nations Systems* (UNEG, 2016) include 14 norms and 24 standards. This quality framework is intended to strengthen and harmonize evaluation practice within the U.N. system, especially with regard to developing national-level capacities for evaluating progress toward the Sustainable Development Goals (United Nations, 2015). Despite the focus on the U.N. system, these standards are intended to be used beyond the U.N. and benefit the global evaluation community. The norms represent overarching principles and values. The standards are more specific statements about how organizations, evaluation managers and commissioners, and evaluators should uphold the norms in practice.

The first ten norms are described as “general norms for evaluation.” These include *Internationally Agreed Principles, Goals and Targets; Utility; Credibility; Independence; Impartiality; Ethics; Transparency; Human Rights and Gender Equality; National Evaluation Capacities; and Professionalism*. The last four norms are “institutional norms for evaluation in the United Nations System.” These include *Enabling Environment; Evaluation Policy; Responsibility for the Evaluation Function; and Evaluation Use and Follow-Up*.

The 24 standards are organized into five categories: *Institutional Framework, Management of the Evaluation Function, Evaluation Competencies, Conduct of Evaluations, and Quality*. The latter two are the most relevant for judging the quality of specific evaluations. The eleven standards under *Conduct of Evaluations* explain that evaluations should:

- be timely and reflect specific intentionality
- be informed by evaluability assessments
- be guided by clear terms of reference
- have clearly defined and feasible scope and objectives
- employ rigorous methods
- engage stakeholders in evaluation planning and implementation
- address human rights and gender equity by both (1) assessing these aspects of programs being evaluated and (2) ensuring the evaluation itself is supportive of human rights and gender equity
- be conducted by competent and diverse evaluation teams selected through transparent processes
- generate reports and other products that are responsive to users' needs and include evidence-based findings, conclusions, and recommendations
- include realistic, evidence-based recommendations
- be communicated and disseminated effectively to enhance use

The final three UNEG standards are under the heading of *Quality*. These standards call for quality assurance systems for evaluation, especially at the design and final stages of evaluation.

Idiosyncratic criteria and connoisseurship in metaevaluation

Metaevaluators and/or stakeholders may opt, based on a metaevaluation's overarching purpose or what they want to learn from it, to use criteria different from or additional to those represented in widely accepted evaluation quality frameworks. Such criteria may be developed specifically for the metaevaluation or drawn from other sources. For example, suppose a metaevaluation involved assessing the degree to which an evaluation was carried out with cultural competence. In that case, a metaevaluator could use the resource that the Centers for Disease Control and Prevention developed that links the Program Evaluation Standards to specific strategies to increase and demonstrate cultural competence (CDC, 2014). In some cases, an issue of interest may be the degree to which an evaluation adheres to a specific theoretical approach to evaluation, such as utilization-focused evaluation (Patton, 2008), empowerment evaluation (Fetterman and Wandersman, 2018), or program-theory-based evaluation (Chen, 2015; Donaldson, 2007). In these cases, the tenets of those approaches could be treated as metaevaluation criteria (Scriven, 2009). However, it should be noted that these idiosyncratic criteria are sometimes contested among evaluators and stakeholders, depending on their professional values, methodological persuasions, and philosophical leanings.

Regardless of the criteria one uses in metaevaluation, it is almost unavoidable that there be a connoisseurial (Eisner, 1983) dimension to it. That is, to some extent, metaevaluators must bring to bear their own expert knowledge about evaluation, in combination with what they learn about a particular evaluation through additional means. Datta (1999, p. 346) called this the “I know it when I see it” approach to metaevaluation. Extensive data collection and explicit guidelines for interpreting metaevaluative data are not always practical for metaevaluations, especially ones that examine a single evaluation.

Metaevaluation methods

The methods used in a metaevaluation—including the types of data selected and how they are collected, analyzed, and interpreted—depend on the metaevaluation's purpose and scope. For example, a formative evaluation intended to improve the primary evaluation must involve examining evaluation plans and materials before they are finalized. In contrast, a summative evaluation would necessarily examine final evaluation products. A metaevaluation of multiple evaluations, whether a few or hundreds—must

include systematic procedures for extracting and coalescing consistent information about each evaluation, including steps to calibrate multiple raters, if applicable.

Evaluation reports serve as an important data source in metaevaluation because they are typically the most prominent deliverables related to primary evaluations. However, evaluation reports are rarely adequate for judging the overall quality of evaluations. There is an inherent difference between a report designed to meet the needs to a primary evaluation's stakeholders and one designed to convey all the information needed for a thorough metaevaluation. Long, highly technical reports tend to be counterproductive to the aim of making evaluations readily useful to stakeholders. Yet, it's often the technical details that are needed in order the technical details in order to judge an evaluation's technical adequacy, among other important aspects of its quality. Further, not all relevant aspects of an evaluation can be conveyed well in a written report. For instance, appropriate treatment and engagement of stakeholders is a common criterion across many of the evaluation quality frameworks discussed above, but this aspect of evaluation is difficult to describe in a written report; it is more easily understood through interviewing stakeholders about their experience with the evaluation. Reports are rarely adequate for comprehensively judging the overall quality of evaluations.

Next, we review methods and procedures recommended by prominent evaluation scholars. The relevance of some of these methods depends on whether the metaevaluation is examining one or several evaluations, the stakes involved and decisions in the balance, and the pertinent metaevaluation questions and criteria.

Metaevaluation methods recommended by stufflebeam

Stufflebeam (Stufflebeam, 2001; Stufflebeam and Coryn, 2014) recommended a metaevaluation approach that involves eleven tasks which parallel the tasks in primary evaluation. Stufflebeam and Coryn suggested these generic tasks (listed in Table 2) be used as a heuristic when planning metaevaluations. They pointed out that some metaevaluations may omit some tasks or include other tasks not on this list.

Metaevaluations, whether formative or summative, should almost always examine evaluation documents, such as plans, meeting minutes, instruments, protocols, and reports—i.e., the “pertinent available information” mentioned in Task 6, as defined by Stufflebeam and Coryn. However, documentation cannot tell the full story about an evaluation. That is why Task 7, which calls for the acquisition of additional information, is often warranted. Additional information may be collected through various means, such as interviews, focus groups, surveys, and observations.

Metaevaluation methods recommended by Cook and Gruder

Cook and Gruder's (1978) typology of metaevaluation approaches offers a different way to conceptualize metaevaluation methods. They argued that primary considerations are whether the metaevaluation occurs after a primary evaluation or concurrently, whether data collected for the primary evaluation are manipulated, and whether there are one or multiple data sets. They organized the possible options into seven basic approaches for metaevaluation:

1. Essay review of an evaluation report;
2. Review of the literature about a specific program;
3. Empirical reevaluation of an evaluation or program;
4. Empirical reevaluation of multiple data sets about the same program;
5. Consultant metaevaluation;
6. Simultaneous secondary analysis of raw data; and
7. Multiple independent replications (p. 17).

Table 2 Generic metaevaluation tasks.

1. Staffing	Staff the metaevaluation team with one or more qualified evaluators.
2. Stakeholder engagement	Identify and arrange to interact with the metaevaluation's stakeholders.
3. Standards	Agree on standards, principles, or criteria to judge the evaluation system or particular evaluation.
4. Questions	Define the metaevaluation questions.
5. Formal agreements	Issue a memo of understanding or negotiate a formal metaevaluation contract.
6. Existing information	Collect and determine the adequacy of pertinent available information.
7. New information	Collect new information as needed.
8. Analysis and synthesis	Analyze and synthesize the obtained information.
9. Reaching conclusions	Judge the evaluation's adherence to appropriate standards, principles, and/or criteria.
10. Reporting	Convey the metaevaluation findings through reports, correspondence, oral presentations, workshops, and other means.
11. Follow-up	As appropriate, help the client and other stakeholders interpret and apply the findings.

From Stufflebeam and Coryn (2014, p. 644).

This typology influenced early conceptualizations of metaevaluation. However, it does not reflect important developments in evaluation over the past 40+ years. For example, Cook and Gruder developed their typology before the first edition of the Program Evaluation Standards was published in 1981, so it lacks references to these or other standards for judging evaluations. Nonetheless, the range of options suggested by Cook and Gruder is broader than what is offered by more contemporary writings on metaevaluation, and persons interested or engaged in metaevaluation would be well served by revisiting this seminal work.

Metaevaluation methods recommended by Scriven

Scriven (2013) suggested three options that substantially overlap Cook and Gruder's (1978) typology:

1. Replicate the evaluation using the same methods and compare results.
2. Evaluate the same program using different methods and compare results.
3. Apply the Key Evaluation Checklist (Scriven, 2013), the Program Evaluation Standards (Yarbrough et al., 2011) or the United States Government Accountability Office (2011) standards to the evaluation.

The first two of these recommended methods and their correlates in Cook and Gruder's typology are applicable to summative metaevaluations for assessing a primary evaluation's accuracy. Scriven (1975) recommended a procedure for reaching convergence when independent evaluations of the same program are conducted. He said the involved evaluators should critique each other's reports, then modify their own based on the feedback. This process is critical for achieving metaevaluative objectives. Otherwise the client just has two evaluations of the same program, which may or may not agree. However, from a feasibility standpoint, it seems unlikely that many evaluation clients would be willing to pay for two full evaluations of the same program at the same time.

Metaevaluation practice

What does real-world metaevaluation practice look like? There have been few systematic investigations into the extent and nature of metaevaluation practice, but even these limited offerings provide useful insights.

Jacob and Affodegon (2015) described 28 metaevaluations published between 1980 and 2012. Across this period, they identified four generations of metaevaluation, which they defined as follows:

1. The *Development Period* (early 1970s to early '80s) was marked by attempts to define and clarify the concept of metaevaluation.
2. The *Propagation Period* (early 1980s to early '90s) was characterized by efforts to understand how metaevaluation should be practiced.
3. The *Enrollment Period* (mid-1990s to mid-2000s) was a time of generating quality frameworks, metaevaluation instruments, and actual metaevaluations
4. The *Maturity Period* (mid-2000s to 2012) was characterized by further codification, adoptions and adaptations of the Joint Committee's Program Evaluation Standards across regional and national VOPEs, and two peaks of activity in terms of the number of published metaevaluation reports annually.

Cooksy and Caracelli (2009) reviewed 18 metaevaluations of single evaluations that they located via evaluation listservs, journals, school websites, and professional contacts. They used these examples to describe and reflect on issues in selecting and applying metaevaluative criteria in metaevaluation practice. Among these 18 studies,

- 17 were summative
- most used multiple data sources, with evaluation reports being the most common source of data about the primary evaluation
- more than two-thirds included reviews of primary evaluation data
- two were conducted internally
- half used narrative reviews and five used checklists
- most used emergent criteria instead of predefined criteria; only four used the Joint Committee's Program Evaluation Standards
- all but one came from three university-based evaluation centers and graduate programs.

From their review, Cooksy and Caracelli concluded it was not clear that metaevaluation had become standard practice.

Motivated by intuition that metaevaluation practice was more common than suggested by these reviews of metaevaluation, this article's third author commenced an ambitious study to examine the extent and nature of metaevaluation practice over half a century (1969 to 2019). (Harnar et al., 2022). A robust search of scholarly and gray literature resulted in 2660 unique materials with the word *metaevaluation* in their title, abstract, or executive summary. Of these, 194 were true positive empirical examples of metaevaluation, indicating that metaevaluation is far more commonplace than suggested in previous reviews.

A review of a subset (nonrandom) of 27 of these metaevaluations published between 2000 and 2019 provided a preliminary view of metaevaluation practice in the education sector. The majority of published educational metaevaluations were external, summative metaevaluations of program evaluations. The metaevaluations assessed multiple evaluations and multiple aspects of those evaluations, including design, process, and results. Most used the Joint Committee's Program Evaluation Standards, either indirectly or explicitly, as their criteria for metaevaluative reasoning and made individual value-claims for each criterion. Data collection methods across these metaevaluations were diverse. Document review was the most common method, followed by

interviews, checklist application, surveys, and observations. These metaevaluations were typically conducted after the primary evaluation concluded, but some took place concurrently. Most made recommendations about the primary evaluations, and some included recommendations about conducting metaevaluation.

Next, we describe four examples of metaevaluations to illustrate the range of ways metaevaluations are carried out.

New York integrated learning system metaevaluation

Finn et al.'s (1997) metaevaluation was a hybrid formative and summative metaevaluation that took place both during and after the evaluation of the New York City Public Schools Integrated Learning System Project (Miller, 1997). It was conducted by an external metaevaluation team and written for diverse audiences, including schools, district offices, the state board of education, parents, community leaders, and the broader evaluation and educational research community. The metaevaluation was intended to "help these audiences assess the evaluation report and draw warranted conclusions about the merit and worth of the Integrated Learning Systems Project" (Finn et al., 1997, p. 159). Specifically, its purpose was to determine "the extent to which the overall study and each sub-study fulfilled the requirements of each of the 30 Joint Commission [sic] Standards" (p. 161). Accordingly, the metaevaluation used as metaevaluation criteria the second edition of the Program Evaluation Standards, which at the time included the domains of *Utility*, *Feasibility*, *Propriety*, and *Accuracy* (the *Accountability* domain was added in 2011). The metaevaluators used a robust assortment of procedures for data collection, analysis, and reporting:

- periodic reviews of evaluation plans, processes, and data
- site visits to observe the project's operation
- discussions with the primary evaluation team and other stakeholders about interim data, stakeholders' information needs, and findings from the formative metaevaluation
- systematic assessment of the final evaluation report and associated materials against the Program Evaluation Standards
- discussions by the metaevaluation team in order to reach consensus about findings and the contents of the metaevaluation report

The metaevaluation team concluded the primary evaluation met requirements for the *Feasibility*, *Propriety*, and *Accuracy* standards, but that the performance of the evaluation for the *Utility* criteria was "marginal" (p. 159).

Metaevaluation of a technology literacy program in underserved communities

This summative metaevaluation assessed an evaluation of an out-of-school-time technology literacy program (Rodríguez-Campos and Ashford, 2015). Specifically, the metaevaluation sought to "assess the evaluation's purpose and questions, in addition to its methods, strengths, and weaknesses" (p. 3). The metaevaluation addressed these five questions:

1. What is the nature of the report?
2. To what extent is the report technically sound?
3. To what extent are the reports [sic] useful?
4. To what extent did the report employ ethical procedures?
5. To what extent was the evaluation method practical? (p. 6)

The external metaevaluation team used Stufflebeam's (1999) Program Evaluation Metaevaluation Checklist to judge the quality of the primary evaluation based on their review of its final report. Stufflebeam's metaevaluation checklist is based on the 1994 version of Program Evaluation Standards by the Joint Committee on Standards for Educational Evaluation (Note that Questions 2 and 3 above parallel the Program Evaluation Standards domains of *Accuracy*, *Utility*, *Propriety*, and *Feasibility*). The checklist includes multiple checkpoints for each standard. Users are instructed to indicate whether the primary evaluation met each checkpoint and use the checklist's scoring guide to reach conclusions about the evaluation quality within each domain.

The metaevaluators adapted the checklist's scoring guidelines by using both a "conservative" and "moderate" approach. Their conservative scoring approach assumed that all information needed to assess the evaluation based on the checklist would be included in the evaluation report and that all checkpoints were relevant. The moderate approach allowed for a more liberal interpretation, acknowledging that some checkpoints may not be relevant or justifiably not be addressed in the evaluation report. The metaevaluators reported their conclusions based on both approaches. According to their conservative analysis, they rated the evaluation's *Utility* as "fair" and its *Feasibility*, *Propriety*, and *Accuracy* as "good." Using the moderate approach, they judged the evaluation's *Utility* and *Accuracy* as "very good" and its *Feasibility* and *Propriety* as "excellent." Ultimately, they synthesized these results and concluded that the evaluation was credible and high quality.

Responsive metaevaluation of the Appalachia regional comprehensive center's evaluation of a capacity-building program

Sturges and Howley's (2017) formative metaevaluation of the evaluation of a "five-year program to build a state department of education capacity to implement federal education law" (p. 126) took place concurrently with the primary evaluation. The metaevaluation merged standards-based metaevaluation, similar to the first two examples in this section, with a primary evaluation

approach of responsive evaluation (Stake, 2004). The metaevaluation's purpose was to "build evaluator capacity, enhance the evaluation's quality, optimize evaluation use, and minimize conflict" (Sturges and Howley, 2017, p. 126).

The metaevaluators described eight steps that closely resembled those recommended by Stufflebeam (Section "Metaevaluation methods recommended by Scriven" of this article; Stufflebeam, 2001; Stufflebeam and Coryn, 2014). However, their final two steps reflect the responsive and iterative nature of their metaevaluation approach.

Their Step 7 was to "facilitate dialogue, deliberation, and agreement" (p. 131). They explained that this involved two types of "facilitated events." They engaged the evaluation teams in periodic reflection sessions to "examine challenges and create plans to remedy them" (p. 131). They also held annual planning retreats to review the year's completed evaluation work, discuss its strengths and weaknesses, and set objectives for the next year.

Their Step 8 was to "review and refine the metaevaluation" (p. 131). In essence, this step was meta-metaevaluative in nature. The metaevaluators sought feedback about the strengths and weaknesses of their work (i.e., the metaevaluation) and made adjustments to be responsive to their stakeholders' needs.

The metaevaluation criteria were derived from the Program Evaluation Standards (Yarbrough et al., 2011), Stufflebeam's (1999) Metaevaluation Checklist, and the American Evaluation Association's (2018) Guiding Principles for Evaluators. After engaging stakeholders to review and prioritize criteria from these sources, the metaevaluators created a matrix that represented the "collectively agreed-upon set of criteria, expectations, and critical success factors for the evaluation" (p. 129). It also listed the sources of information for the metaevaluation, which included document reviews, interviews, surveys, and observations. Like Stufflebeam's metaevaluation checklist, it included a five-point rating scale for each criterion.

Due to the formative, iterative, and concurrent nature of the multi-year metaevaluation, there was no single final metaevaluative synthesis. Instead, the metaevaluators delivered annual reports with their quality ratings and recommendations to the primary evaluators and the project's leadership, along with periodic "targeted feedback briefs" (p. 134).

Metaevaluation of HIV/AIDS program evaluations using the African evaluation guidelines

This metaevaluation included 14 evaluations of HIV/AIDS-related programs funded by UNICEF and UNAIDS across nine African countries (Patel, 2002). Its purpose was two-fold: (1) identify opportunities to improve evaluations of HIV/AIDS-related programs and (2) pilot use of the then-new African Evaluation Guidelines (AEG) (Nairobi M&E Network et al., 2002) on a large scale. The metaevaluation applied 20 of the 30 guidelines that made up the 2002 AEGs. The other ten were not included because, Patel explained,

Some of the Guidelines are best used *ex ante* since some aspects of quality cannot easily be assessed after the fact. Some guidelines required information that was not available in the papers submitted for publication. For example, it was often difficult for the reviewers to assess the local 'Political viability' of an evaluation (p. 330).

Using the prompt, "How well did each evaluation meet the guidelines?" three reviewers independently rated each of the 14 evaluations on the 20 relevant guidelines using a six-point (0–5) rating scale. Compiling the evaluations' scores across the 20 guidelines in a table enabled the team to compare their relative strength and weakness.

Across all the guidelines, the median scores for the set of 14 evaluations were either 3 or 4, except for the guideline of *Values Identification* under the *Utility* domain, which scored a 2. Patel observed that the low scores in this area were "especially troubling" and a "serious weakness" given that "variations in cultural and social values play a significant role in the [HIV/AIDS] epidemic" (p. 330).

Summary

Metaevaluation serves several important functions for a wide range of evaluation stakeholders. Formative metaevaluation helps evaluators ensure their work is relevant and technically sound. Summative metaevaluation adds credibility to primary evaluations and helps evaluation audiences gauge how much confidence they should place in the findings. Ascriptive metaevaluation, as a vehicle for research on evaluation and theory-building, aids in enhancing the evaluation discipline's self-knowledge and developing more sophisticated models and tools for evaluation. Independently, each type of metaevaluation represents what Scriven (1969, p. 36) referred to as the practical role of metaevaluation: to evaluate "specific evaluative performances." Collectively, these metaevaluation efforts contribute to our knowledge about what constitutes sound evaluation practice, where evaluation discipline falls short of what it strives to accomplish, evaluation's role in contributing to the betterment of society, and how to advance the discipline. This is what Scriven described as the theoretical function of metaevaluation, which goes beyond looking at particular evaluations to "the evaluation of the very function and practice of evaluation itself" (Fitzpatrick et al., 2004, p. 443).

Introduction

Continuing emphasis on the fundamental—but not particularly new—idea that teachers working and learning together can enhance the quality of learning and teaching in schools has led to widespread international interest, focusing on the potential of professional learning and professional learning communities (PLCs) to advance school improvement. For over 15 years this approach has been a key thread in England's Department for Education (DfE) National Standards for Head teachers and teachers' professional development (DfE, 2020, 2016). Research studies in a range of international contexts, particularly in the USA, Netherlands and more recently China, have similarly emphasized the value and role of professional learning communities to enhance professional practice (Stoll and Louis, 2007; Hipp et al., 2008; Slegers et al., 2013; OECD, 2016; Hairon et al., 2017; Thomas et al., 2017; Zhang and Sun, 2018; Zahedi et al., 2021). Effective PLCs are seen as more likely to generate and support sustainable improvements in student and other outcomes because they build the necessary professional skill, capacity, and shared good practice. However, can the effectiveness and quality of a PLC be measured, and does it have a quantifiable positive impact on pupil

[☆] Change History: March 2022. S.M. Thomas updated the text and references throughout this entire article, updated the article title and added new Tables 2, 4 and 7.

outcomes? Although relatively few research studies address these specific questions, this article draws on the available evidence and reports in detail selected findings from two PLC studies conducted in UK and China. The first is a large-scale research project funded by the UK's Department for Education and Science (DFES), General Teaching Council (GTC), and National College for School Leadership (NCSL) 'Creating and Sustaining Effective Professional Learning Communities (EPLCs)' (Bolam et al., 2005). The second is a similar research project funded by UK Economic and Social Science Research Council (ESRC)¹ and UKAID 'Improving Teacher Development and Educational Quality in China (ITDEQC)' (Thomas et al., 2015). In particular, both the EPLC and ITDEQC projects illustrate the quantitative research tools used to define and measure specific aspects of PLCs and examines the relationship between these measures and pupils' academic outcomes. At this point, it is important to point out that the term professional learning community, used in this article, overlaps with—but is, nevertheless, more focused on—professional staff learning, than the term school learning community which is, generally, seen as broader and refers to all learners in the school community.

Three approaches to evaluate schools as professional learning communities

One common approach to evaluating schools as professional learning communities is to examine the school characteristics and processes that have been identified as key features of a PLC. International research suggests that PLCs are characterized by five aspects: shared values and vision; collective responsibility for pupils' learning; reflective professional inquiry; collaboration; and the promotion of group, as well as individual learning (Stoll et al., 2003, 2006a; Hord, 1997; Louis et al., 1996). However, further research identified three new characteristics and four processes relevant to the creation and effective functioning of PLCs (Bolam et al., 2005). Therefore, although PLCs do not look exactly the same in all schools, research has found that they seem to display eight characteristics which—irrespective of the educational phase or context—they exhibit to a greater or lesser degree:

1. Shared values and vision;
2. Collective responsibility for pupils' learning;
3. Collaboration focused on learning;
4. Individual, group, and collective professional learning;
5. Reflective professional enquiry;
6. Openness, networks, and partnerships;
7. Inclusive membership; and
8. Mutual trust, respect, and support.

In addition, four processes are required to create and sustain a PLC:

1. Optimizing resources and structures to promote the PLC;
2. Promoting individual and collective professional learning;
3. Evaluating and sustaining the PLC over time; and
4. Leading and managing to promote the PLC.

A range of professional development activities have been developed drawing on these 8 characteristics and 4 processes to assist school leaders and staff in reviewing, evaluating and sustaining their own school as a PLC (Stoll et al., 2006b). Other more recent research has explored the benefits of PLC interventions to support professional development in Dutch schools (Admiraal et al., 2021) as well as sought to further refine the PLC as a multidimensional construct (Hairon et al., 2017).

A second approach to evaluating schools as professional learning communities is to use survey and statistical techniques to identify and examine a finite set of key indicators or factors related to the processes of continuing professional development (CDP) and, more broadly, to the development of PLCs. This approach has been used in a study in the Netherlands by Visscher and Witziers (2004) who identified six PLC concepts (policy and evaluation; consultation and cooperation; consensus; decision-making, school leadership; and departmental leadership) and measured these via a teacher questionnaire administered to mathematics teachers in 39 schools. Pedder et al. (2005) have also explored the nature of professional learning via a factor analysis of teachers' responses to a questionnaire and identified four factors related to teacher learning. The factors were:

1. *Inquiry*. Using and responding to different sources of evidence; carrying out joint research and evaluation with colleagues.
2. *Building social capital*. Learning, working, supporting, and talking with each other.
3. *Critical and responsive learning*. Through reflection, self-evaluation, experimentation, and by responding to feedback.
4. *Valuing learning*.

One purpose of this kind of approach is to establish the existence of one or more factors that could be useful as summary indicators to measure and evaluate particular aspects of schools' capacity and success in developing as a PLC. More recent research has similarly sought to examine and refine PLC measures in different country contexts in Europe and East Asia (Slegers et al., 2013; Pang et al., 2016; Chen et al., 2016; Lomos, 2017; Zhang and Sun, 2018; Antinluoma et al., 2018). Importantly, indicators of this type could provide helpful feedback to inform school self-evaluation and improvement processes (see, e.g., Scheerens et al., 2003). This is

¹This research is supported by ESRC/UKAID funded projects Improving Educational Evaluation and Quality in China (RES-167-25-0353) and Improving Teacher Development and Educational Quality (RES-167-25-0428). See <http://ieeqc.bristol.ac.uk>

illustrated in greater detail below by presenting selected results from the EPLC questionnaire survey used to test out the relevance of different characteristics and processes of PLCs in different kinds of schools in England (Bolam et al., 2005) and equivalent findings from the ITDEQC study conducted in China (Thomas et al., 2015).

A third and, arguably, the most revealing approach to evaluating schools as professional learning communities is to examine the relationship between the indicators of PLCs and a range of pupil outcome data to establish whether or not the extent of school characteristics and processes that are associated with PLCs are also linked to improved student outcomes. There is some evidence with regard to the impact of continuing professional development—and, more generally, of PLCs—on student outcomes and progress (see, e.g., Lee and Smith, 1996; Louis and Marks, 1998; Wiley, 2001; Vescio et al., 2008; Lomos et al., 2011; Hofman et al., 2015; Doğan and Adams, 2018). However, findings in this area can be illustrated by both the EPLC study (Bolam et al., 2005), and the more recent comparable ITDEQC study in China (Thomas et al., 2015; Thomas, 2020) which provide rare opportunity—via the collection of school-questionnaire—survey data alongside access to the national pupil-assessment databases and school value added measures—to produce some relatively hard data. The nature of this data is, of course, correlational—not causal—but, nevertheless, this evidence is arguably more robust than many studies and is employed in this context to illustrate, in detail, the findings and methods used to evaluate the effectiveness of PLCs in terms of promoting student outcomes.

Characteristics and processes of schools as PLCs

As noted above, previous research in England has identified eight key characteristics and four processes relevant to the creation and sustainability of schools as PLCs. The study conducted by Bolam et al. (2005) employed both case-study and questionnaire-survey methods to draw its final conclusions. However, the detailed findings from the questionnaire administered to almost 400 English schools provide a useful example of the most and least common PLC features reported by schools.

The questionnaire was developed from a review of the literature on PLCs and was designed to be completed by the headteacher or CDP coordinator of each school participating in the study—in consultation with other staff. The questionnaire comprised three parts:

- *Part 1.* Items designed to gather opinions regarding aspects of PLC in the school; these questions are framed in terms of the proportion of staff in the school engaged in particular activities or having particular views. These items reflect different aspects of CDP and teachers' professional life: teacher support for pupil learning; professional learning; support for professional learning; collaboration and culture; research and professional enquiry; external links and networking; and participation of teaching assistants and nonteaching support staff in PLC.
- *Part 2.* Items exploring the perceptions of a definition of a PLC and the factors that the respondent felt facilitated, or were barriers, to the school becoming a PLC.
- *Part 3.* Items related to factual information with regard to the range and extent of professional development and school self-evaluation activities in the school.

The questionnaire findings indicated which PLC characteristics and processes the respondents were most and least likely to report, on average—in terms of the proportion of staff engaged in particular PLC activities, as well as which activities were the most and least variable across schools—thereby suggesting agreement among schools on the importance of some key PLC features (see Table 1).

The findings show that two question items are crucial in terms of primary and secondary schools reporting the highest mean level of teacher involvement. These are: collective responsibility for pupil learning and creating conditions for pupils to feel the confidence to learn. Responses to these two items also demonstrate a high level of consensus among schools, given the low item-score variability in comparison to other items. These findings suggest, not surprisingly, that pupil learning is the foremost concern of teachers, and that this PLC characteristic is very common in all schools.

In contrast, the results for two different items (experience job rotation and have opportunities for work shadowing) indicate that both primary and secondary schools, typically, reported a low level of teacher involvement in these activities. The finding suggests that these particular aspects of CDP related to learning and developing staff roles, were not a common characteristic in most schools. Finally, the results for two further items (have dedicated time for classroom observation and have some protected time for joint planning and development) suggest that, although a medium level of staff involvement is reported by primary and secondary schools, there is a notable lack of consensus (i.e., high item-score variability) concerning these two activities across schools. This finding suggests that some aspects of CDP—concerned with improving classroom practice—are very variable across English schools, with some schools reporting a high level of staff involvement and others reporting a low level of staff involvement. The issues of teachers' time management and professional culture may have an impact here.

Interestingly by comparing similar part 1 teacher survey results indicating the extent of staff engagement in PLC activities from England (EPLC project) and China (ITDEQC project), out of 34 equivalent questionnaire items, head teacher/CPD coordinators' responses were mostly found to rank similarly (see Table 2). However, three items (set learning targets for individual pupils; routinely share information with parents; and the community; and Non-Teaching support staff actively contribute to the school as a PLC) were ranked much higher by English than Chinese respondents (difference in ranking >16) in terms of the greater extent these activities were observed by head teachers/CPD coordinators in school. In contrast, four items (carry out classroom-based research; have dedicated time for classroom observation; engage in team teaching; and Non-Teaching Support Staff (NTSS) share

Table 1 Perceived aspects of PLC by primary schools and secondary schools: Extent of staff engagement for the three items (indicated with the original questionnaire numbers) with the highest/lowest means and standard deviations (England; EPLC project).

	<i>Mean</i>	<i>Standard deviation</i>	<i>n</i>
Highest mean—primary schools			
Q1: Collective responsibility for pupil learning	3.77	0.56	224
Q3: Create conditions for pupils to feel the confidence to learn	3.74	0.52	225
Q4: Learn together with colleagues	3.73	0.51	223
Highest mean—secondary schools			
Q1: Collective responsibility for pupil learning	3.64	0.54	164
Q3: Create conditions for pupils to feel the confidence to learn	3.40	0.61	164
Q24: are members of at least one professional team	3.80	0.55	160
Lowest mean—primary schools			
Q9: Carry out classroom-based research	1.81	1.00	209
Q36: Experience job rotation	1.83	1.07	214
Q38: Have opportunities for work shadowing	1.75	1.03	215
Lowest mean—secondary schools			
Q36: Experience job rotation	1.13	0.34	160
Q38: Have opportunities for work shadowing	1.36	0.71	157
Q44: Receive financial support from the school for award-bearing courses	1.42	0.85	153
Highest standard deviation—primary schools			
Q13: Have dedicated time for classroom observation	2.48	1.25	222
Q44: Receive financial support from the school for award-bearing courses	1.95	1.26	207
Q45: Have some protected time for joint planning and development	2.57	1.37	218
Highest standard deviation—secondary schools			
Q13: Have dedicated time for classroom observation	2.28	1.13	162
Q43: Use professional development profiles/portfolios	2.41	1.14	158
Q45: Have some protected time for joint planning and development	2.36	1.18	163
Lowest standard deviation—primary schools			
Q1: Collective responsibility for pupil learning	3.77	0.56	224
Q4: Learn together with colleagues	3.73	0.51	223
Q18: Share a common core of educational values	3.71	0.55	225
Lowest standard deviation—secondary schools			
Q1: Collective responsibility for pupil learning	3.64	0.54	164
Q24: are members of at least one professional team	3.80	0.55	160
Q36: Experience job rotation	1.13	0.34	160

Only includes items from the PLC survey part 1. The four-item response categories indicating the extent of staff engagement are treated as a numerical scale from one to four as follows: nearly all staff (>80%) = 4, most staff (50–80%) = 3, some staff (20–49%) = 2, a few staff (<20%) = 1. Adapted from Bolam et al. (2005).

responsibility for pupil learning) were ranked much higher by Chinese than English respondents (difference in ranking >16) in terms of the greater extent these activities were observed by head teachers/CPD coordinators in school. The findings suggest that PLCs in England and China may operate similarly overall, but some key elements such as PLC involvement of parents and non-teaching staff, and the opportunities for team teaching, classroom observation and research may differ (see also Qiao et al., 2018; Chen, 2020). Importantly this suggests that context specificity may be a critical issue when considering the nature and contribution of PLCs in supporting teacher development in different country contexts, and points to the need for new research exploring the usefulness of PLC concept in different education systems.

Stages of PLC development

Schools in the English EPLC sample were found to be adequately representative of the national picture in terms of context factors, such as the percentage of pupils in the school entitled to free school meals. However, it is important to note that schools were asked specifically, in part 2 of the survey, to assess their current stage of development as a PLC. The provisional working definition of a PLC quoted in the survey was as follows: “An effective professional learning community has the capacity to promote and sustain the learning of all professionals and other staff in the school community with the collective purpose of enhancing pupil learning.”

Table 2 Comparison of findings from England (EPLC project) and China (ITDEQC project): high (1–12) and low (23–34) ranked items based on 34 similar PLC survey questions regarding extent of teachers/ staff engagement with PLC activities.

	<i>Rank: China 2010</i>	<i>Rank: England 2003</i>
1. Shared values and vision		
Share a common core of educational values	1	6
2. Collective responsibility for pupils' learning		
Collective responsibility for pupil learning	2	2
Non-teaching support staff (NTSS) share responsibility for pupillearning	5	23
Pupil learning		
Set learning targets for individual pupils	27	5
Ensure pupils receive constructive feedback about their work	3	11
3. Collaboration focused on learning		
Engage in team teaching	8	31
Have dedicated time for classroom observation	9.5	26
Regularly discuss teaching methods	7	8
Have opportunities for work shadowing	25	33
Learn from each other	11.5	9
4. Individual, group and collective professional learning		
Receive training in how to work and learn in teams	28	25.5
5. Reflective professional practice		
Carry out classroom-based research	11.5	32
6. Openness, networks and partnerships		
Use university staff for professional learning	34	34
Use professional/subject associations for professional learning	30	28
7. Inclusive membership		
Routinely share information with parents and the community	31	7
Non-teaching support staff (NTSS) are valued by teachers	6	1
NTSS actively contribute to the school as a professional learning community	29	12

Note: Different but comparable item scales were used: China (never = 1; Always = 5); England (1 = <20% staff; 4 = >80% staff). For both EPLC and ITDEQC project the survey was designed to be completed by one respondent—CPD coordinator/head teacher. EPLC sample: secondary schools $n = 164$; ITDEQC sample: 98 senior secondary schools from 3 west/east LEAs.

Table 3 Percentage of English EPLC schools reporting different stages of PLC development.

<i>PLC stage</i>	<i>Nursery and primary schools (n = 227) %</i>	<i>Secondary schools (n = 166) %</i>
Mature/established	25	16
Developer	57	67
Starter	14	15
Working to reestablish PLC	2	1
No response	2	1

Note: The primary and the secondary school samples included special schools, respectively. Adapted from Bolam et al. (2005)

Most respondents—57% from nursery and primary schools and 67% from secondary schools—reported that their school was a developing PLC (see Table 3). Therefore, the EPLC survey findings reported above reflect the features of this self-reported group of schools more than any other. Moreover, it is important to note that the survey findings are a summary of data collected at one point in time from one respondent in each school—either the head or CDP coordinator—responding to the survey. Of course, the situation may have changed since the data were collected and, in addition, other members of the school may have different opinions concerning the questions. Clearly, these issues should be considered when interpreting the survey findings, although interviews in case-study schools—also conducted as part of the study—generally confirmed survey respondents' perceptions of their school's current stage of PLC development.

To contrast with the EPLC findings from English schools, where almost all questionnaire participants recognized their school at least to some extent as a PLC, the findings from China indicate that not all teachers agree that a 'Whole' school PLC exists in this school (see Table 4). Regardless of the three locations (LEAs in two central and one west region of China), 80% of teachers or more

Table 4 ITDEQC Teacher questionnaire 2012: Existence of PLCs in Chinese senior high schools.

Percentage response to item: "Whole school PLC exists in this school"	Strongly disagree	Disagree	Uncertain	Agree	Strongly agree
LEA1	1.3	3.2	16.5	61.1	18.0
LEA2	4.6	2.2	12.2	50.6	30.4
LEA3	0.9	4.4	22.5	54.7	17.5

Note: (i) calculated using individual teacher level data; (ii) sample size = LEA1 (8093), LEA2 (7608), LEA3 (1814) with item missing values less than 2% for total sample (17,515).

either agree or strongly agree that PLC is a meaningful concept in Chinese schools. However, the results are up to ten percent lower in terms of whether a PLC actually exists in their own school. Maybe not surprisingly LEA3 in the poorer west of China reported the lowest percentages on these issues, suggesting the greatest uncertainty regarding the PLC concept and the strength of traditional CPD approaches. This again highlights the need for new research exploring the usefulness of PLC concept in different education systems, and ways in which it might need to be adapted for different country contexts such as China.

Summary indicators of PLCs

In addition to the questionnaire-item results outlined above, the EPLC study of English schools also provides a useful example of findings that employ quantitative factor-analysis techniques to establish the existence of one or more summary indicators or factors that could be used to measure and evaluate schools as professional learning communities. Four independent factors were identified from the EPLC questionnaire results which relate to:

- Factor 1: professional and pupil learning ethos;
- Factor 2: within-school policy, management, and support for professional learning;
- Factor 3: enquiry orientation (external and internal); and
- Factor 4: participation of nonteaching support staff in PLC.

As an illustration of the results, the questionnaire items loading on Factor 1 (professional and pupil learning ethos) are shown in [Table 5](#) (for further details, see [Bolam et al., 2005](#)).

Correlations between the EPLC factor scores showed that, although there is some overlap between factors (i.e., all correlations are positive), there are, nevertheless, observable differences between these PLC summary indicators. Therefore, the evidence indicates that at least four dimensions reflecting different aspects of PLCs exist and individual schools can have a very different profile of results across the four factors. The factor findings related to professional and pupil learning, and enquiry orientation are also

Table 5 EPLC questionnaire items included on the factor of "professional and pupil learning ethos".

<i>Factor 1 professional and pupil learning ethos</i>
1 Collective responsibility for pupil learning
2 Base their approach to change on the use of good evidence
3 Create conditions for pupils to feel the confidence to learn
4 Learn together with colleagues
5 Ensure pupils receive constructive feedback about their work
6 Set learning targets for individual pupils
7 Routinely collect, analyze, and use data and evidence to inform their practice
8 Have low expectations of children
9 Actively seek and use feedback from pupils
10 Regularly monitor the learning and progress of individual pupils
11 Share a common core of educational values
12 Use the staff room at break times for professional links
13 Are involved in seeking solutions to problems facing the school
14 Regularly discuss teaching methods
15 Share their professional experiences and successes
16 Experiment and innovate in their work
17 See the school as stimulating and professionally challenging
18 Routinely share information with parents and the community
19 Learn from each other
20 Take responsibility for their own professional learning
21 Give priority to learning more about pupils learning

reflected in a comparable questionnaire study which focused specifically on professional learning and was conducted on the basis of a teacher survey—over 1000 individual teacher responses from 32 schools (Pedder et al., 2005). As previously noted, in the study carried out by Pedder and his colleagues, four factors were identified using standard factor-analysis techniques which comprised aspects of inquiry and using different sources of evidence, building social capital, critical and responsive learning, and valuing learning. Broad similarities could also be found with the PLC concept factors identified by Visscher and Witziers (2004).

Contrasting the extent of PLCs in primary and secondary schools

The validity of the PLC concept at the primary and secondary phases of education was also examined by Bolam and colleagues in terms of whether English schools from different educational phases report similar levels of staff involvement as measured by the PLC factors. Table 6 depicts the mean and standard deviation of the standardised factor scores from primary and secondary schools. Overall, the findings indicate that primary schools, generally, report higher levels of staff involvement in PLC processes than secondary schools. Interestingly, the highest level of primary-phase staff involvement suggested by the factor scores is in terms of pupil and professional learning ethos (Factor 1). In contrast, for the secondary phase, the highest level of staff involvement is in terms of enquiry orientation (external and internal; Factor 3).

As discussed above, in the EPLC survey, respondents were also asked to assess their current stage of development as a PLC in three developmental stages: mature/established, developing, and starting the journey to become a PLC. The validity of conceptualizing PLCs in three stages was examined by looking at the relationship between schools' four-factor scores and their self-reported stage as a mature, developer, or starter. In some cases, the findings suggest an overlap between mature and developer PLCs—with starter PLCs falling behind on some factors. In addition—not surprisingly—in all cases, the primary school mean factor score for a particular PLC stage is higher than the equivalent secondary school mean factor score, again reflecting the overall tendency for primary schools to have reported higher teacher PLC involvement than secondary schools.

Given these findings, it is not clear whether it should necessarily be expected that primary and secondary phases would report a similar level of staff involvement in the PLC. This is because secondary schools are, usually, much larger and it is possible that smaller PLCs exist within the schools surveyed but were not identified because the focus was at the whole-school level. For example, one or more secondary school subject departments may operate as a PLC and display the characteristics and features of a mature PLC, but the proportion of total school staff involved may be low.

Nevertheless, overall—from these findings—it appears that whole-school PLCs within English secondary schools may be less developed than those within primary and nursery schools, because the results indicate that a smaller percentage of staff are perceived to be engaging in the measured PLC behaviors. Of course, such a response pattern is not uncommon in questionnaires of this type (e.g. McCall et al., 2001), and achieving secondary school improvement is notoriously more difficult than that in primary schools (Louis and Miles, 1990).

Overall, the results from the four PLC factors do appear to be broadly in line with schools' self-reported stage of development—in all cases, schools reported as mature PLCs have higher average factor scores than starter PLCs. Despite this, it is also important to point out that by combining the results from different questionnaire items into summary indicators (i.e., factor scores), a greater degree of differentiation can be employed in measuring each factor than the three crude PLC developmental stages of mature, developers, and starter. This evidence does seem to suggest that the conceptualization of a PLC needs to shift from the idea of a single dimension in three developmental stages to multiple dimensions—each being on a continuum—although the two approaches could also be seen as broadly complementary.

Relationship between pupil outcomes and PLC processes and contexts

The EPLC research conducted by Bolam and colleagues also provides evidence of the relationship between the characteristics of PLCs and pupil outcomes and these findings address the crucial question of whether there is a statistically significant relationship

Table 6 Means and standard deviations of the four PLC factor scores by educational phase.

	Educational phase			
	Nursery and primary schools n 227		Secondary schools n 165	
	Mean	Standard deviation	Mean	Standard deviation
Learning ethos (factor 1)	0.29	0.94	−0.41	0.95
Support for professional development (factor 2)	0.28	1.03	−0.38	0.82
Enquiry orientation (factor 3)	0.22	1.06	−0.32	0.81
Participation of nonteaching staff (factor 4)	0.26	0.82	−0.36	1.12

Factor scores were standardized across the whole sample with mean 0 and standard deviation 1. The primary and the secondary school samples included special schools, respectively. Adapted from Bolam et al. (2005).

between school PLC indicators (e.g., factor scores) and school academic performance measures. As outlined in greater detail below, only tentative evidence of a positive relationship has been found. Nevertheless, the findings support previous research by several researchers. Lee and Smith (1996, p. 103) found that “Achievement gains are significantly higher in schools where teachers take collective responsibility for students’ academic success or failure rather than blaming students for their own failure. Achievement gains were also higher in schools with more cooperation among staff.” Louis and Marks (1998) found that the promotion of a professional community for teachers has a positive relationship with the organization of classrooms for learning and the academic performance of students. Similarly, Wiley (2001) found a positive effect for professional community on student achievement—but only in situations where teachers’ experience of (transformational) leadership was also positive. In line with meta-analyses conducted by Vescio et al. (2008) and Lomos et al. (2011), a more recent study by Doğan and Adams (2018) comparing 13 international studies also reported evidence to support the conclusion that participation in PLCs results in improved teacher practice and increased student achievement. However, they highlight that there are methodological challenges in some PLC studies that limit interpretation of results which still need to be addressed.

Arguably, the most rigorous approach to evaluate the effectiveness of PLCs in promoting student outcomes involves sophisticated statistical analyses (multilevel modeling) conducted to establish whether or not there is a statistically significant relationship between schools’ value added in terms of pupils’ relative progress and their capacity as a PLC. Crucially, despite the limitations that apply to all numerical measures, longitudinal value-added (VA) measures of relative pupil progress provide a more valid measure of educational and school effectiveness than the raw results (Thomas and Mortimore, 1996). However, for comparison purposes, raw (unadjusted) assessment and examination results are typically also employed—as published in the annual league tables in the UK.

Calculating VA and raw school performance

In the EPLC project a variety of different multilevel models were tested prior to deciding on the final ones to use for calculating VA school performance (e.g. see Thomas, 2001). This approach was seen as preferable to assess the long-term VA impact of a school on a pupil’s progress in learning and attainment as the models utilize outcome and baseline data that span, by and large, the period spent in that school phase by pupils. However, both the VA and raw (unadjusted) models have been used to analyze the end of phase schooling outcomes. The Outcomes for primary schools comprise the mean National Curriculum Key Stage 2 (KS2) assessment score across the core subjects of English, mathematics, and science for 11-year-olds. Outcomes for secondary schools comprise the Total National Curriculum Key Stage 4 (KS4) assessment score, including grade scores for all subjects taken by 16-year-olds in the General Certificate for Secondary Education and in General National Vocational Qualifications (GCSE/GNVQ). The final multilevel VA models take account of the variability in pupil outcomes due to the characteristics of the pupil intake for a school. Thus, pupils’ prior attainment, gender, socioeconomic background, and other variables are controlled for in the statistical analysis (see Bolam et al., 2005). The VA score (or residual) for each school is determined from the model results and used to make more robust (reliable) comparisons about how pupils in a school perform compared with pupils in other schools. The raw model is used to calculate school performance in terms of raw pupil outcomes when no adjustment for intake and other factors has been made.

Correlations between school performance and PLC indicators

The four EPLC factors were correlated with primary and secondary schools’ VA and raw performance. However, only a minority of these comparisons were found to be statistically significant at the 0.05 level and the findings are summarized below (see, Bolam et al., 2005, for further details of statistical results). At the primary level, positive and statistically significant correlations were found between schools’ Factor 1 score professional and pupil learning ethos and their 2002 KS2 performance—both raw and VA. At the secondary level, positive and statistically significant correlations were also found for both Factor 1 professional and pupil learning ethos and Factor 2 support for professional learning—but only in terms of schools’ VA GCSE/GNVQ performance. Of course, it should be noted that the relationships are fairly weak (no correlations reported are greater than 0.3). However, it could be argued that this would be expected, given that any statistical relationship is likely to be tenuous between process measures collected as a snapshot at one point in time and pupil performance and progress over a relatively long time period (4–5 years).

The relationship between pupil outcomes and the individual items from part 1 of the survey, were also examined. As expected, the findings support those from the EPLC factor results reported above. Several positive and statistically significant correlations (at 0.05 level) were found, but only two were fairly strong ($r > 0.3$) and these relate only to the primary phase (teachers have low expectations of pupils and teachers share a common core of educational values—note that both of these items are included on Factor 1). There are only three items that are statistically significant (at 0.05 level) across both the primary and secondary phases and the evidence tentatively indicates that these aspects of a PLC are key in terms of enhancing pupil progress. Positive relationships were found between schools’ VA scores and their responses to the following three items: teachers create the conditions for pupils to feel the confidence to learn, teachers share a common core of educational values, and teachers see the school as stimulating and professionally challenging. A positive relationship (at the 0.05 level) was also found between primary VA scores and one additional item: teachers’ experiment and innovate in their work.

Correlations between school performance and PLC factual characteristics

The relationship between pupil outcomes and the PLC factual characteristics, from part 3 of the survey, were also examined in the EPLC project involving English schools. Both positive and negative statistically significant correlations (at 0.05 level) were found—six indicating a fairly strong relationship ($r > 0.3$). These six strongest correlations were found between pupil outcomes and items related to the status of the school—that is, being in an Education Action Zone or part of an Excellence in Cities initiative (negative relationships) or being a Beacon School, having other working links or Specialist status (positive relationships). Thus, a school's involvement in these kinds of initiatives seems to be related to school performance and effectiveness. A school being in an Education Action Zone or Excellence in Cities initiative indicates that it receives additional funding and support due to being located in a particularly economically disadvantaged area. Beacon School or specialist status indicates that a school has met the criteria for excellence and/or additional resources in particular aspects of the curriculum.

In addition, interestingly at the primary level, weak but nevertheless statistically significant positive associations were found between school VA outcomes and the degree to which staff were monitoring pupil progress. This finding supports previous research that underlines the need for systematic monitoring of pupil progress in schools to improve school effectiveness (Thomas et al., 2007). At the primary level, the total number of supply teaching days for 2001/02 was also significantly negatively correlated with raw pupil outcomes suggesting that frequent teacher absences have a detrimental effect on pupil outcomes.

Finally, in addition to the correlational analyses described above, further multilevel analyses were also carried out to determine whether the previously identified PLC factors and other school characteristics have a combined (as well as individual) impact on pupil progress in the VA models (i.e., given pupil intake factors have already been accounted for in the analysis) and whether they further reduced the remaining unexplained school and total variance. In line with the correlational analyses, it was found that, in the primary school analyses, the addition of Factor 1 professional and pupil learning ethos to the VA model was statistically significant (at the 0.05 level); however, this resulted in a very small reduction in school and total variability in KS2 mean score outcomes. Similarly, in the secondary school analyses, the addition of both Factor 1 professional and pupil learning ethos and Factor 2 internal support for professional learning into the VA model, was statistically significant. However, overall, the findings indicated that any positive link between school PLC factors and pupil outcomes is fairly weak and may be difficult to distinguish when other (possibly confounding) school factors and context—such as percentage of pupils entitled to free school meals—is taken into account. In summary, these findings are interesting as they do suggest that a weak, but positive, link exists between individual PLC factors and pupil outcomes—particularly, VA performance, which measures the relative progress of pupils in a school in comparison to pupils in other schools, arguably one of the most valid measures of school effectiveness.

As a further illustration of the relationship between pupil VA measures and PLC/CPD factors, equivalent ITDEQC evidence from one region in an affluent central area of China (LEA1) is reported in Table 7. The findings are tentative and identify association not causality but provide additional support regarding the type of CPD variables that seem to be most significant in explaining secondary student examination outcomes in Chinese, Mathematics and English, once student prior attainment, background and school context have been controlled for in analyses. There is a mixed pattern of positive and negative statistically significant results for CPD factors, which makes the interpretation somewhat difficult given negative results may suggest that more CPD activities are being undertaken because student outcomes are relatively low. Nevertheless, there appear to be more positive than negative impacts associated with CDP factors, including: number of formal CPD hours, participation in CPD related to research projects and new teaching methods, and CPD factors related to collaboration and resources or support. Overall, these results from China ITDEQC project are quite encouraging given, alongside the EPLC findings reported above, they suggest that some CPD activities do appear to have a statistically significant association with students VA progress at school. Moreover, the significant factors seem to be those typically associated with the concept of professional learning communities—such as teacher collaboration.

Providing a more rigorous analysis, correlational and multilevel modeling findings of the kind reported above are important because, arguably, particular PLC and CPD factors can only be validated as effective if a positive impact on student progress and outcomes can be demonstrated. On the other hand, it may be that quantitative measures used in the research conducted so far are not sufficiently sensitive to fully reflect the complex relationship among PLCs and pupil performance and progress. Therefore, further research is necessary to extend the knowledge base in a broader range of contexts and contribute stronger evidence on this issue which has only rarely been addressed using sophisticated quantitative techniques.

Conclusion

In conclusion, a limited number of relevant studies have been reviewed and the findings indicate that some key PLC characteristics in England are more (or less) commonly reported in schools (e.g., opportunities for work shadowing and experience job rotation were, generally, less common). In addition, some key PLC characteristics are more-or-less variable among some schools than others (e.g., dedicated time for classroom observation and protected time for joint planning and development were more variable). These findings reveal an important message for policymakers—that there are some key areas of teachers' professional development that either happen very infrequently in schools or are highly variable across schools. Moreover, evidence comparing PLC characteristics in England and China indicates that context specificity is an issue, pointing to the need for the PLC concept to be refined and adapted in different country contexts.

Table 7 Statistically Significant teacher questionnaire CPD variables related to value added performance (2012).

<i>CPD variables</i>	<i>LEA1</i>		
	<i>Chinese</i>	<i>English</i>	<i>Maths</i>
Total formal CPD hours		+	
Total informal CPD hours			
Participation in qualification program			
Participation in a network of teachers formed			
Participation in individual or collaborative research			
Participation in mentoring and/or peer observation and coaching	-		-
Participation in reading professional literature			-
Participation/Engaging in informal dialogue with your colleagues			+
Participation in research project, writing papers		+	+
Participation/Engaging in activities and planning			
Participation in how to teach in a multicultural setting			
Participation in instructional strategies and teaching methods	+	+	
Participation in teaching content and performance standards			
Participation in class management	-		
Participation in student discipline and behavior problems			
Participation in how to counsel students			
% CPD activities at school level	+	+	
Factor of perceived future CPD need related to student development and class management			
Factor of perceived future CPD need related to curriculum and teaching methods			
Factor of frequency appraisal received			
Factor of CPD through collaboration and feedback	+	+	
Factor of CPD through educational resources and support			+

Note: CPD variables (– negative coefficient; + positive coefficient) statistically significant (0.05) in explaining student outcomes (University entrance examinations), once student prior attainment, background and school context have been controlled for in the multilevel model (VA Model Xc). LEA1 sample: Schools 40 teachers 326 Pupils 28,197. See [Thomas \(2020\)](#) for further details of analyses.

Regarding PLC measurement, the [Bolam et al. \(2005\)](#) and other similar studies found that the summary indicators of different aspects of a PLC can be identified using quantitative factor-analysis techniques. However, it is important to recognize that the different factors identified are not, necessarily, comprehensive for the purpose of evaluating the nature and quality of PLCs. The qualitative case-study data, also reported by [Bolam et al. \(2005\)](#), tapped into considerable detail and depth concerning the nature of PLCs and, subsequently, revealed important new aspects of PLC processes and characteristics such as trust and distributed leadership, which were not directly included on their questionnaire survey. Moreover, in Bolam and colleague's final conclusions, it was suggested that PLCs should be evaluated not only in terms of pupil outcomes—indeed, overall the quantitative evidence linking student outcomes and PLC functioning, although positive seems to be fairly weak—but also via impact on staff morale and practice, and potential for developing leadership capacity, as well as by establishing that PLC characteristics are in place and processes are operating smoothly. Further research is, of course, needed to explore these issues in more detail, given that future theory building will require stronger evidence of this kind to clearly differentiate between the effects of the wide varieties of learning, development, and improvement activities that teachers, schools, and PLCs engage in.

This article indicates fairly strongly that a school, as a PLC, is multidimensional and complex in nature. Evidence also, tentatively, suggests that some PLC characteristics and processes may be enhanced or hindered by the advantages or disadvantages of particular contexts (e.g., smaller size may allow greater opportunities for collaboration, higher percentage of student disadvantage indicated by their eligibility for free school meals may indicate higher funding levels for professional development activities). The idea of three developmental stages (mature, developer, and starter) may be helpful as a starting point in understanding the PLC concept but, in the end, may be too crude to measure the complexity of PLC characteristics and processes. This article demonstrates that a more detailed approach is needed to help teachers and other professionals working in schools to understand the conditions

and contexts that underpin systematic and effective professional learning as well as to enhance PLC development in schools. Further evidence is also needed to better understand the links between professional learning and the learning of other members of the school community—such as students and parents—to explore whether the processes and outcomes of a PLC mirror those of the school learning community as a whole. Interestingly, fruitful areas of new research have also developed the idea of PLCs to look more at external links via Networked Learning Communities (Katz and Earl, 2010; Poortman et al., 2021; Prenger et al., 2019) and Research Learning Communities (Dimmock, 2016; Rose et al., 2017).

Overall, the review findings indicate that quantitative and qualitative methods can be used to evaluate different aspects of the effectiveness and quality of a PLC and demonstrates the potential for creating valid measures of professional learning within schools in England, China and elsewhere. These kinds of measures could provide a useful method of enhancing information available to schools and, if used alongside other types of evidence, could meaningfully inform school improvement and self-evaluation activities (see Stoll et al. (2006b) and ITDEQC (2018) for examples of PLC evaluation materials produced for use in English and Chinese schools).

Introduction

One of the most crucial problems that almost all educational systems around the world are facing concerns the need for developing an effective teacher evaluation system based on a valid theoretical framework. Existing teacher evaluation systems fail to either identify effective teachers (Flores and Derrington, 2018; Rockoff, 2004; Sanders et al., 1997) or contribute to teacher professional development (Creemers et al., 2013). This is mainly because links between teacher evaluation policies and research on educational effectiveness and improvement have not been established. The use of empirical evidence in introducing or implementing new mechanisms of teacher evaluation can be questioned (Huber and Skedsmo, 2016). Hallinger et al. (2014) argue that the policies and politics driving teacher evaluation processes remain considerably stronger than the empirical evidence. Consequently, existing teacher evaluation systems are not able to promote educational quality since they are unable to support teachers become more effective and through that promote student learning outcomes (Peterson, 2000; Weisberg et al., 2009). Thus, by pursuing policymakers to establish an effective teacher evaluation system in their countries, will eventually enhance each country's educational outcomes since student achievement may be promoted.

Teacher quality is seen as the highest priority factor for affecting student achievement (Hattie, 2009; Looney, 2011; Nye et al., 2004; Muijs et al., 2014) and studies in educational effectiveness research (Coleman et al., 1966; Gordon et al., 2006; Rivkin et al., 2005; Rockoff, 2004; Muijs and Reynolds, 2011) describe the importance of maintaining high quality of teaching so that students can improve their learning outcomes. Therefore, the field of educational effectiveness turned its focus on elaborating on the features of teacher evaluation (Mortimore, 2001). However, the field has become rather ethnocentric, with groups of scholars working in different countries pursuing isolated agendas, largely uninfluenced by the agendas in other countries (Reynolds et al., 2002; Chapman et al., 2016). This situation can partly be attributed to the lack of specific criteria for measuring teacher effectiveness (Kyriakides and Campbell, 2003). Unless the criteria for evaluating teachers emerge from tested theories on teacher and school effectiveness, evaluators cannot be held accountable for how their judgements about teacher performance have been arrived at. The main theoretical models of teacher effectiveness research (TER) can be seen as a source for generating a set of criteria for teacher evaluation that captures the multiple teacher roles in changing the educational environment.

Teacher evaluation can be described as "the systematic assessment of a [teacher]'s performance and/or qualifications in relation to a professional role and some specified and defensible institutional purpose" (Gullickson and Howard, 2009, p. 27). Teacher evaluation is seen as a systematic process, which means that it is purposeful, it requires preparation, and specific products/outcomes are expected to occur (Liu, 2011). Consequently, data on teachers' performance need to be collected and analyzed through precise methods even if the tools for collection and the type of data collected might differ. Moreover, teacher evaluation should aim to improve teachers' professional development by providing them with an understanding of both how they are performing based on the expectations and what needs to be done to perform better (Tarhan et al., 2019). Nowadays, educational policies are introduced to evaluate teachers and their performance to achieve public accountability of schools and teachers (Huber and Skedsmo, 2016). Nevertheless, a second aim of teacher evaluation is the development of teachers and their practice. Teacher evaluation processes may assess not only individual teacher performance but also the achievement of school and/or educational system goals (Stronge, 2006b; Hallinger et al., 2014). These different approaches to teacher evaluation are formed by the relative emphasis education systems place on the use of results for either accountability (e.g., high-stakes rewards and/or sanctions) and/or for improvement purposes (e.g., professional development targeted to identified needs and support for innovation) (Looney, 2011; Robertson-Kraft and Zhang, 2018). Thus, it is important to set priorities on features of evaluation that are more important than

others and to investigate which combinations of policies and actions situated on different levels enhance educational effectiveness, so as to establish successful reforms on evaluation.

In this context, the main elements of a comprehensive teacher evaluation system are described in the next section of this chapter. In the third section of the chapter, we argue for establishing meta-evaluation mechanisms when designing a teacher evaluation system. In the fourth section, an overview of the findings of a recent meta-analysis of 156 international studies on teacher evaluation is provided pointing out the main aspects that should be taken into account when conducting research to design a valid and reliable evaluation system. In the last section of the chapter, implications for research, policy and practice on teacher evaluation are drawn.

Developing a comprehensive teacher evaluation system

There are three main aspects that need to be taken into account when developing a comprehensive teacher evaluation system: (1) *the evaluation purposes*, (2) *the evaluation criteria* and (3) *the sources for collecting relevant data* (Ellett et al., 1996). It is important to note that the establishment of criteria depends on the rationale for which the evaluation is conducted and on the availability of appropriate sources of data, thus all three main aspects are interrelated (Kyriakides et al., 2006).

Evaluation purposes

A *twofold purpose of teacher evaluation* is recognized in the literature (see Barile et al., 2012; Kimball et al., 2004; Rigby, 2015; Steinberg and Donaldson, 2016; Santelices and Taut, 2011; Vekeman et al., 2015; Zhang and Ng, 2011) since teacher evaluation is intended to hold teachers accountable (i.e., summative purpose) and/or to help them in their professional development (i.e., formative purpose). These two general functions of any teacher evaluation system may refer to more specific aims that might include licensing/credentialing, tenure, self-assessment, and professional development (Beerens, 2000; Harlen and James, 1997; Stronge, 2006a). Sometimes combinations of purposes may apply to a teacher evaluation system, contributing to either completing multiple tasks or creating unnecessary deficiency to the initial task. This is because, on the one hand, the accountability purpose reflects the need to verify the ability of teachers to ensure that services delivered are effective, and this has typically been considered to be summative in nature, and, on the other hand, the improvement purpose reflects the need for the professional growth and development of the individual teacher, and typically has been considered to be formative in nature. Further to the summative purpose, teachers are held accountable (by rewarding and/or “punishing” them) based on their students’ performance, and it is implied that this will improve their effectiveness (Amrein-Beardsley, 2014; Papay, 2012; Paufler, 2018). Accountability-focused evaluations regularly tend to rate and rank teachers and these practices are, thus, used to develop decisions related to compensation and staff issues (Goldstein, 2014). Summative assessment practices were found, though, to have a negative impact on teachers, especially on psychological aspects such as increased pressure (Collins, 2014) and reduced morale (Collins, 2014; Paufler, 2018).

When teacher evaluation is used for formative purposes, evaluation is related mainly to the provision of constructive feedback that contributes to teachers’ professional growth and improvement (Glickman et al., 2014). This form of teacher evaluation can have invaluable positive effects on teacher instructional practices (Delvaux et al., 2013; Taylor and Tyler, 2012). Moreover, teachers have indicated that a combination of practices such as classroom observations accompanied with formative feedback was crucial for improving teacher performance and their morale for teaching (Anast-May et al., 2011). Although there are studies reporting on the frequent use of feedback and its positive outcomes (Prado Tuma, et al., 2018), other researchers emphasize the lack of such an approach during the evaluation process (Donaldson, 2012, 2016; Weisberg et al., 2009). It can, therefore, be claimed that teacher evaluation without formative feedback is unlikely to improve the quality of teaching (Goe et al., 2012; Papay, 2012).

However, it is practically impossible that the dual character of evaluation can be achieved within a single teacher evaluation mechanism, since determining the evaluation purpose inevitably influences the design of the evaluation methods and instruments, as well as the interpretation of the results (Black and Wiliam, 1998; Kyriakides et al., 2021). Given that, a comprehensive system of teacher evaluation should be built serving both purposes of evaluation, as it is important to give emphasis on both outcomes and improvement (McGreal, 1988), policy makers should be able to establish different mechanisms of formative and summative teacher evaluation. Since the summative and formative purposes of evaluation are based on different value assumptions, different criteria might be used for conducting each type of teacher evaluation. The relevance of the teacher evaluation criteria cannot be judged without the purpose for which evaluation is conducted being made explicit. However, in order for the teacher evaluation systems to serve both purposes, there must be a rational link between them (Stronge, 1995); this should not allow the summative function of evaluation to dominate the formative function, as the experiences of many countries seem to reveal (e.g., Ellett et al., 1996; Kyriakides et al., 2018). Additionally, this link cannot be established, unless the criteria for both the formative and summative evaluation mechanisms are based on the same theoretical framework concerning what constitutes an effective teacher. Consequently, in the next part of this section, we argue on generating criteria for teacher evaluation.

Evaluation criteria

Several sources could guide the development of *evaluation criteria*, including teachers’ job descriptions and their professional code (Johnson, 1997), the theoretical models of TER (Cheng and Tsui, 1999), as well as teachers’ opinions (Patterson et al., 1986; Firestone, 1989). However, in many countries there is a lack of professional code and the teacher’s role is vaguely described. Also, each

country according to its teaching tradition may contain different value assumptions on teacher evaluation, thus creating a universal set of criteria is not an easy task. Therefore, we argue that TER could be the basis upon which measurable criteria of teacher evaluation could be established since the characteristics of effective teachers and their multiple features in the educational environments are captured through the different theoretical models of teacher effectiveness (Fessler and Ungaretti, 1994; Kyriakides et al., 2002; Murphy, 1995). These theoretical models are presented below in an effort to outline both the advantages and disadvantages of using each model to generate criteria for teacher evaluation. Identifying the strengths and weaknesses of employing the various TER models in developing criteria for teacher evaluation, helps policy makers to take advantage of their best features and determine well-suited evaluation mechanisms for each context.

- (a) *Goal and Task Model*: The goal and task model conception of teacher effectiveness is based on the formation of aims and tasks that are justified through the achievement level of students. A distinct advantage of this model is the fact that goals and tasks are defined accurately. This model has also the advantage that the outcomes of teachers' performance are easily observed since policymakers could evaluate teachers directly based on their students' learning outcomes. In this sense, performance standards should exist. Indicators of teacher effectiveness that may arise through such an approach include achievement of teaching objectives, fulfilment of job specifications, performance standards, student learning outcomes and many more (Cheng and Tsui, 1999). Furthermore, the model relies on the genuine effort of teachers to achieve their goals and teacher effectiveness is set to be perceived to the extent that educators are able or not to reach the goals initially set. This model could express the demands of summative evaluation as it enables evaluators to examine specific dimensions of the teachers' work and thus offers the possibility of comparable results. Despite the obvious advantages of the model, a series of concerns might arise when applying this evaluation model mainly concerning fairness issues for setting complicated or numerous tasks in small time frames as well as employing methods that are not pedagogically appropriate but help students to achieve the expected goals. Moreover, questions are raised on the types of goals that are meaningful both for the school and teachers and on who is responsible for setting these goals (Kyriakides et al., 2020).
- (b) *Working-Process Model*: The working process model emphasizes on the smooth teaching and working processes. This model is basically supporting that a number of educational actions by teachers such as effective teaching and the learning process occurring to students are fulfilling the predetermined objectives measured through the various types of students' learning outcomes. Hence, effective teachers are described as those that can ensure the quality of their teaching (Creemers and Kyriakides, 2008). This model refers to the "process-product" model, which is responsible for the classification of a range of teacher behaviors, which are linked to the improvement of student achievement gains (Brophy and Good, 1986; Doyle, 1986; Everston et al., 1980; Galton, 1987). Factors that seem to carry evidence of significance are quantity of instruction and likewise, the pace of instruction (Brophy and Good, 1986). In this model, effective teachers are those that are able to create a learning environment in their classroom that promotes their students' learning outcomes (Creemers and Reezigt, 1996; Doyle, 1986). Under this condition, student achievement is linked to variables that refer to the form and quality of teachers' educational planning and instruction, such as structuring of the lesson, asking questions (soliciting), providing feedback (reacting) and providing opportunities to engage students in the learning process (Kyriakides and Demetriou, 2007). Therefore, this model could be appropriate to assess teachers according to their teaching behaviors, the classroom environment that they create, their willingness to participate in decision making and the working relationship with other key actors in the school. However, it is implied that by using this model as the unique source of teacher evaluation may not provide valid results on examining the appropriateness of the educational aims initially set. This is because there are questions regarding to what standards are teachers who operate in different contexts evaluated and how are these standards related to students' progress, given that students have diverse instructional needs, due to their different learning styles and personality types.
- (c) *Resource-Utilization Model*: The resource utilization model refers to a more bureaucratic approach and is based on the use of allocated resources and acquisition of inputs to produce a desirable output. In this model, it is made clear that the relationship of resources to teaching and its outputs is established, so as to explain an effective teacher evaluation process. Teachers are expected to complete numerous tasks in their school, usually under time pressure. Hence, the provision of the appropriate resources is considered of crucial importance for maximizing teacher effectiveness. According to this model teachers need to utilize existing resources but also, locate new resources, especially when there is evidence of linking those resources with achieving desirable outcomes. However, there are questions related to the kind of resources to be used, the availability of them, if they are sufficient for the whole staff of each school and most importantly if these resources facilitate teacher performance and education outcomes.
- (d) *The School-Constituencies Satisfaction Model*: This model links teacher quality with "client (e.g. students, parents) satisfaction", which is basically demonstrated through the clients' expectations and demands. Teachers are considered effective when their performance satisfies the students and parents (Peterson et al., 2000). This is a model that could provide solutions on the weaknesses of the other theoretical models, due to the various criteria for evaluating teachers that it contains, based on the different needs of the various education stakeholders. However, when employing this model, there are issues that need to be considered such as who are the key stakeholders that strongly influence school functioning and teachers' work and how their different needs and expectations can be related to the predefined objectives and duties of the teachers.
- (e) *The Accountability Model*: The focus of this model is to demonstrate competence and responsibility of teachers in their instruction and other educational practices in school in conjunction with related professional decisions. This model is based on the assumption that the overall quality of the educational system is ensured by demonstrating evidence of accountability

(Scheerens, 2013). Therefore, this model is in various aspects similar to the school-constituencies model, since effective teachers are identified by the satisfaction that they provide to other stakeholders involved in the educational process. The concept of this model requires that teachers are reporting to the various school constituencies about their work, the decisions they make and their standards. To that end, the usefulness of the model relies on the case that teachers are requested to provide evidence of accountability, or even further, in the case that a process of monitoring or evaluation occurs, accountability measures are the focus for many educational systems. The present model includes new factors to teachers' evaluation such as keeping social and school stakeholders informed on the progress of schools' performance. These kinds of factors may raise negative reactions from teachers since there is a high possibility of perceiving this form of monitoring as an intervention in their professional role.

- (f) *The Absence of Problems Model*: This model constitutes that the absence of problems in the duties of teachers creates a framework of effectiveness. Accordingly, effective teachers are defined as those who satisfy the minimal requirements, for example the personnel that do not cause any problems or conflict by their actions in their professional environment and furthermore are able to cope with conflicts that may arise in the school environment. The usefulness of this model relies on the specification of certain criteria for teacher evaluation referring to certain problematic areas of schooling. The model is mainly used by evaluators to identify weaknesses and problematic aspects of school life and make suggestions for improvement.
- (g) *The Continuous Learning Model*: This model assumes that teacher professional development is linked to school improvement (Fullan and Hargreaves, 1992) and that professional development programs can help teachers become more effective. The model proves to be effective especially in cases where teachers change educational settings and are in need of adapting to constant new challenges. Evaluators, though, should have in mind that teachers' adjustment to new school environments may not be the single reason for improvement, and before setting up any type of professional development, they need to be sure that these changes derive from existing program objectives.

Sources for collecting relevant data

In terms of the *sources for collecting evaluation data*, high performance educational systems nowadays tend to prefer multiple sources of data for evaluating their personnel. This multidimensional approach for collecting different types of data (see Danielson and McGreal, 2000) may increase the internal validity of an evaluation system (Cronbach, 1990). Studies in the field of TER stress the need for implementing multiple methods for assessing the impact of teachers' instruction upon student achievement as it aims at gaining a greater variation of teacher effectiveness. Such methods include techniques like classroom observations, value-added measures of the contribution of individual teachers, student ratings and self-evaluation processes (see Creemers and Kyriakides, 2012; Creemers et al., 2010). Classroom observation is widely recognized as a mean to teacher evaluation and teacher development. Observational systems in which quality observational instruments, well-trained raters, and vigorous scoring designs are combined, can produce reliable teacher scores (Hill et al., 2012). To achieve this, generalizability theory (Brennan, 2001; Cronbach et al., 1972; Marcoulides, 1989; Shavelson and Webb, 2006) can assist in the design of observation systems that produce reliable scores. This is because, generalizability theory can provide a comprehensive framework for making decisions about the multiple elements of observational systems and provide empirical evidence regarding the optimal number of raters and lessons required to produce desired consistencies. In addition, student ratings of teacher performance can provide information about teachers' behavior in the classroom. As students are direct recipients of the teaching-learning process, they are in a key position to provide information regarding the development of motivation in the classroom, opportunities for learning, degree of understanding and communication developed between them and the teacher (Carle, 2009; Kyriakides et al., 2014; Marsh, 1987). However, in spite of the several strong reasons for using student ratings to evaluate teachers (Lasagabaster and Sierra, 2011), ratings of teacher performance remain suspect as a means of evaluating instructional effectiveness and very little effort has gone into the development of principles and practices in relation to this source of data in primary and secondary education. Nevertheless, there are several effectiveness studies that have shown that primary students are capable of providing valid data on the classroom behavior of their teachers (Bacher-Hicks et al., 2019; Elstad et al., 2017; Kyriakides et al., 2014; Peterson et al., 2000). Of course, it is argued that at the very first stage of analysis of student ratings, researchers need to investigate the generalisability of such ratings, especially when single scores per teacher for each teaching skill are generated.

To conclude, it is important to stress that adopting a multiple-source approach for collecting evaluation data may cause problems of practicality and validity. For instance, evaluators may encounter difficulties in developing psychometric tools based on data gathered from different sources that may incorporate different sources of measurement error associated with each source of data (Kyriakides et al., 2006). Hence, it is a challenge for evaluators to locate the appropriate data sources for an effective teacher evaluation system by selecting the data through a criterion-based approach suggested by theory that supports TER. Thus, it is important that there is transparency on stakeholders' perceptions on the reliability and validity of data collection, before deciding what evaluation scheme should be deployed.

Establishing meta-evaluation mechanisms to support teacher evaluation systems

When designing a teacher evaluation system, monitoring is the key factor of the process for assuring quality of the desired outcomes. Either in the case of setting up a whole teacher evaluation system or redesigning parts of an existing evaluation system, establishing

a quality assurance policy is imperative. Thus, it is important to examine whether evaluation systems set up such meta-evaluation mechanisms so as to identify their strengths and weaknesses and take actions in order to further improve the mechanisms as well as the evaluators' skills to achieve their evaluation aims.

It is not a given that every evaluation system is properly designed, just as it is not a given that the evaluation results are always successful, and the suggestions derived from these results are always valid and reliable. To ensure that an evaluation system is working properly, meta-evaluation procedures should be used (Cooksy and Caracelli, 2009; Stufflebeam, 2011). Scriven (1969) introduced the term "meta-evaluation" underlining the importance of evaluating the evaluation processes, but since then only few educational systems around the world developed meta-evaluation procedures. One can claim that evaluating an educational system or a part of it is a challenging process depending on the policy makers' and various stakeholders' consent. Often teachers and other bodies show a negative reaction to new evaluation reforms hindering their implementation. However, data has shown that the evaluators tend to be more responsible when they know that their performance will be evaluated in the end (Scriven, 2009; Stufflebeam, 2011).

The meta-evaluation procedure has generally a two-fold purpose: (a) to help the evaluators to design, implement, and improve their evaluation system and to properly interpret the evaluation results (formative purpose), and (b) to identify the strengths and weaknesses of an evaluation system (summative purpose). Also, there are two main forms of meta-evaluation that the educational systems seem to apply. First, there is an integrated measure of meta-evaluation, where the process co-exists with the teacher evaluation process but still it is distinctly separated. This form of meta-evaluation is designed alongside the teacher evaluation mechanism; thus, the elements of the evaluation process direct the nature of the meta-evaluation. Evaluators in this concept are mainly external evaluators, but there are also opportunities for enhancing other approaches too. Second, there is an independent form of meta-evaluation where it is composed separately from the main evaluation procedure, initiated by the constituency that ordered the evaluation process in the first place. Choosing the form of meta-evaluation also determines its time of occurrence. Elaborating on the time of evaluation occurrence there are two possible scenarios: a) in the case of integrated meta-evaluation it runs simultaneously with the main evaluation process and b) in the case of independent meta-evaluation there are scenarios where it runs simultaneously alongside to the main evaluation process, but mostly after the completion of it (Fitzpatrick et al., 2004).

Meta-evaluation processes are reported only rarely in the related literature and there is a number of reasons for this. The most important reason is oriented toward the resistance of stakeholders participating in the design of a teacher evaluation process and providing accountability transparency. In this perspective it should also be mentioned that an evaluation process incorporates a wide range of stakeholders. Moreover, the actions of evaluators have either direct or indirect impact on the participating counterparts. Hence, developing meta-evaluation systems causes the political dimension of evaluation to become the main point of discussion (Pfeffer, 1992; Stronge and Tucker, 2000; Fitzpatrick et al., 2004).

To sum up, an effective meta-evaluation system needs to be characterized by a wide consensus among all the interested parties. Decisions should be taken not only by policymakers, but also by other stakeholders that take part in the evaluation process. Creating consensus could be achieved by simulating the impact of meta-evaluation outcomes on the related parties and speculating the probable reactions that may be caused during and/or after its occurrence.

In the next section of this chapter, a brief overview of the findings of a recent meta-analysis of international studies on teacher evaluation is presented. This meta-analysis investigates the extent to which research on teacher evaluation covers the main aspects of the proposed comprehensive framework on teacher evaluation. It also helps readers to identify the international dimension of research on teacher evaluation. Suggestions for further research are also provided in the last section of this chapter.

Meta-analysis of studies on teacher and school evaluation: an overview

Methods

In the first part of this section, the main methods of the meta-analysis such as the selection of studies and the criteria for including specific studies in the analysis, are briefly presented. The way that data from each study were coded and entered in the analysis as well as the estimation of effect sizes of the results reported in those studies investigating the impact of teacher evaluation and the specific information on the multilevel model used to conduct the meta-analysis are not mentioned since this information is beyond the scope of this chapter.

Selection of studies

For the selection of studies included in this meta-analysis we searched documentary databases containing abstracts of empirical studies. The following databases were considered: Educational Resources Information Center, Educational Research Abstracts Online, Social Sciences Citation Index, Educational Administration Abstracts, SCOPUS, ProQuest 5000, and PsycArticles. We also paged through volumes of education-focused peer-reviewed journals with interest in teacher evaluation, teacher professional development, and effective teaching, including the journals "School Effectiveness and School Improvement", "Educational Assessment, Evaluation and Accountability", "American Educational Research Journal", "Educational Management Administration and Leadership", "Educational Policy", "Studies in Educational Evaluation" and "Assessment in Education: Principles, Policy and Practice". The key term "teacher evaluation" was used and a total of 1766 articles appeared as related to the topic. From these articles, 156 were eventually selected as they were relevant to the topic, coming from 29 different countries.

Criteria for including studies

The following two criteria for selecting and including studies were used. First, we only selected studies conducted during the last 20 years (i.e., articles published between 2000 and 2019). At this point it should be noted that more than half of the studies included in this meta-analysis (i.e., 58%) were conducted between 2014 and 2019. This shows an increase of the interest of researchers in conducting studies on teacher evaluation during the last 5 years. Secondly, only empirical studies were selected (e.g., validation, experimental, and longitudinal studies). For example, studies testing the validity of an evaluation system (e.g., Borman and Kimball, 2005; Bradshaw, 2002; Derrington and Campbell, 2018) or instruments used in this system (e.g., Amrein-Beardsley et al., 2016; Koedel et al., 2017; Namaghi, 2010), and/or studies investigating the effectiveness of a teacher evaluation reform (e.g., Taut and Sun, 2014; Tuytens and Devos, 2018; Yoo, 2018) were included in this meta-analysis. The studies that met both criteria were, therefore, included in our analysis ($n = 156$). These studies can be found in the web page www.uci.ac.cy/eeerucy/en/.

Main findings: descriptive analysis

In this part, the main results of the descriptive analysis of the data are briefly presented. These results may help readers understand the international dimension of teacher evaluation and come up with conclusions for the main trends of research on teacher evaluation. The nine findings emerged from this meta-analysis are presented below.

First, teacher evaluation seems to be an international concern, considering the fact that the search for studies concluded to sources from 29 different countries. Although 60% of these studies are reported in North America and the United States, we were able to identify a significant percentage of studies (i.e., 10%) which were conducted in developing countries. It should however be acknowledged that papers coming from developing countries seem to criticize the “borrowing” of teacher evaluation policies established in developed countries. This is clearly stated in the papers included in this meta-analysis. Chile is one of the countries where teacher evaluation policy was based on “borrowing” teacher evaluation policies developed in other countries and especially the United States. It is, however, obvious that the research community has doubts on the effectiveness of such cross-national “policy borrowing”, as regards to their impact on improving teacher evaluation practices in the respective countries.

Second, there are several studies ($n = 26$) conducted in various countries ($n = 8$) that put efforts into changing their existing teacher evaluation systems. These studies aim to evaluate the effectiveness of a teacher evaluation reform and are concerned with the purposes of the teacher evaluation reform ($n = 25$), the criteria of the proposed evaluation system ($n = 26$), and the sources of data that the reform has introduced ($n = 20$). In detail, 96% (i.e., 25 out of 26) of the studies report on the purposes of the newly developed teacher evaluation reforms, whereas 35% (9 out of 26) of the studies refer to summative evaluation purposes and 62% of studies refer to both evaluation purposes (i.e., summative and formative). Consequently, none of the studies was found to refer to systems that were developed on the premise of promoting only the formative evaluation purposes. Moreover, all studies that were found to refer to newly developed systems of teacher evaluation are related to specific criteria of evaluation which are frequently in line with more than one model of evaluation. For example, in this set of studies, evaluation criteria were found to be mostly related with the accountability model (96%), the goal and task model (69%) and the working process model (27%). Also, 77% of studies report on the sources of data that are used in each evaluation system. It is important to note that only few ($n = 7$) of the proposed evaluation reforms address meta-evaluation and this seems to be in line with our argument that meta-evaluation mechanisms should be established in most countries (see third section of this chapter).

Third, almost all the studies reviewed here collected data from either the pre-primary (29%, $n = 46$), primary (80%, $n = 125$) and/or the secondary school level (71%, $n = 111$). No more than 10% of the studies ($n = 16$) are concerned with teacher evaluation in higher education. In each phase of schooling, one can notice that the relevant studies were conducted in various countries and not only in developed countries. For example, studies carried out in pre-primary education did not take place only in the United States, but also in countries such as Chile, China, Finland and the United Kingdom. Similar observations can be drawn for studies carried out in primary education. Most of these studies were conducted in the United States (64%), whereas other studies took place in countries such as Chile, Portugal and the Netherlands. Studies conducted in secondary education also appear in several countries including Chile, China and Belgium. These results reveal that teacher evaluation is a topic of interest for researchers in various countries and interest was given to the role of teacher evaluation in each phase of compulsory education (i.e., pre-primary, primary and secondary education). Despite the fact that most studies were conducted in the United States (i.e., pre-primary: 34 out of 46; primary education: 80 out of 125; secondary education 70 out of 111), researchers in other countries show also an interest on conducting studies about the role of teacher evaluation in each phase of schooling. It should, however, be acknowledged, that only recently studies on teacher evaluation in pre-primary education were conducted. More specifically, more than 70% of studies on teacher evaluation in pre-primary education took place during the last 5 years and 13 out of 46 were conducted in 2019. On the other hand, the number of studies on teacher evaluation in higher education, remains low throughout the year range set in this meta-analysis ($n = 16$). To conclude, the fact that almost 30% of the studies in this meta-analysis report findings concerning pre-primary education, shows the importance of establishing valid teacher evaluation mechanisms from the very early stages of schooling.

Fourth, in regard to the research strategy that each study has used one can identify an uneven number of empirical studies across the eleven types that were detected. More specifically, the most frequent research strategies were (a) cross-sectional studies (26%), (b) studies investigating stakeholder perceptions using the interview technique (16%), (c) mixed-research methods (i.e., combination of qualitative and quantitative measures) (15%) and secondary analysis of large scale studies (13%). Notably, only a limited number of studies (6%) were experimental (either randomization studies or quasi-experimental). Moreover, a very small percentage

of studies (8%) were found to be longitudinal. Countries that concentrate the largest number of studies in the meta-analysis, such as the USA, Chile, Belgium and China tend to use a variation of research strategies, but in each of these countries a very small number of studies were found to use experimental and/or longitudinal research strategies. For example, in the case of the United States, only 10 out of 88 studies (11%) were either experimental or longitudinal.

Fifth, almost all studies included in this meta-analysis (91%) were concerned with the criteria of teacher evaluation. It was, therefore, possible to examine the emphasis that was given to each model of TER in generating evaluation criteria. It was found that most studies, and especially those conducted in the United States, paid attention to the *Accountability model* ($n = 111$) and to the *Goal and Task model* ($n = 100$). An interest to criteria deriving from the *Working Process model* can also be observed ($n = 48$). It is, however, important to note that those studies which were concerned with the *Working Process model*, took place mainly in European countries where teachers are usually not held accountable for their students' learning outcomes. In regard to the other models of TER, very few studies were concerned with criteria deriving from the *Continuous Learning model* ($n = 23$) and almost no studies with the *Absence of Problems model* ($n = 2$) and the *Resource Utilization model* ($n = 1$). It is, however, important to note that 64% of studies (i.e., 98 out of 156) acknowledged the importance of criteria deriving from more than one model of TER. The most common combination of criteria observed in these studies had to do with criteria deriving from the *Goal and Task model* and the *Accountability model* and this combination was mainly observed in studies conducted in the United States, Chile, and China where strong teacher accountability systems seem to exist. Moreover, studies using criteria deriving from the *Continuous Learning model* were also concerned with the importance of criteria associated with either the *Working Process* or the *Goal and Task model*. These results reveal that the research community supports the importance of using more than a single model of TER to generate criteria of teacher evaluation, especially since teachers are expected to take on multiple roles and additional responsibilities, such as curriculum developers, action researchers, team leaders and staff development facilitators. Thus, a broader and multidimensional conception of teacher effectiveness that incorporates measures of effectiveness across these different roles, is necessary.

Sixth, in terms of the sources for collecting teacher evaluation data, these are allocated in two broad categories according to: (a) the authority/stakeholder responsible for providing teacher evaluation data and (b) the methods used for collecting the data. As regards to the first category, headteachers (65%), ministries or other educational agencies (38%) and external experts on evaluation (21%) are mostly reported in the studies included in this meta-analysis. It is acknowledged that 63% of the studies included in this meta-analysis, have used more than one stakeholder (i.e., source) to provide teacher evaluation data. In regard to the techniques used to generate data, questionnaires were often used to collect data, either from students (50%) or from headteachers (33%). It is interesting to note that only 13 out of 156 (8%) studies searched for the extent to which other teachers/colleagues can provide teacher evaluation data. On the other hand, the use of teacher self-evaluation as a technique for conducting formative evaluation was examined by more than 20% of studies. Furthermore, a significant percentage of studies (32%) were concerned with the use of value-added methods to evaluate teacher effectiveness. This technique was observed in countries with a strong teacher accountability system. Finally, more than 3 out of 4 studies (78%), were concerned with the use of more than one source of data. This implies that the research community recognizes the importance of using multiple methods for collecting teacher evaluation data and this trend can be observed in studies conducted in various countries around the world.

Seventh, the studies considered in this meta-analysis were classified into four broad categories depending on the purpose that they served. The four categories are: (1) Evaluation of recent reforms related to teacher evaluation, (2) Validation studies, (3) Investigation of new approaches to teacher evaluation and (4) Investigations of the impact of teacher evaluation on student learning outcomes. It is acknowledged here that there are studies that belong to more than one category. More specifically, 26 studies were found to be situated in more than one category. The most frequent combination ($n = 21$) was found to be studies examining the validity of a teacher evaluation system and at the same time investigating the impact of the evaluation on teacher outcomes and student achievement. Studies that were found to be situated in the first category ($n = 26$) aim at evaluating a reform policy in teacher evaluation and most of these studies were concerned with the perceptions of different stakeholders toward the reform policy ($n = 21$) whereas only 4 attempted to identify the extent to which the reform managed to achieve its aims which implies that the objective evaluation model was rarely used by this group of researchers. On the other hand, studies that are placed in the second category ($n = 121$), seek to investigate the validity of different evaluation tools and/or of existing mechanisms and/or frameworks of evaluation. It is important to note that this area of studies forms the largest set of studies. The third area of studies ($n = 16$) includes the studies that aim to examine new evaluation features and approaches either because of their recent appearance or due to an experimental set up that may provide new insights to all related stakeholders of the educational process. The fourth category of studies ($n = 30$) aims to link teacher evaluation with the ultimate aim of the educational process; the improvement of student learning outcomes. This category includes a very limited set of studies and represents the efforts to measure the impact of teacher evaluation on improving student learning outcomes. Researchers in different countries gave more emphasis to the second category of studies rather than others. For instance, in the United States, more than 75% of studies (66 out of 88) belong to the second category which aims to validate specific mechanisms of teacher evaluation systems. It is finally important to note that in each country, only few studies belonged either to the third or fourth category. However, an interest on reform evaluation studies is only observed in those countries where changes in teacher evaluation mechanisms take place. These results reveal some variation in the interest of researchers in different countries on issues related to teacher evaluation which can partly be attributed to contextual factors.

Eighth, the great majority of studies identified in this meta-analysis are not theory driven. Specifically, only 18% of the studies reported the use of any form of theoretical structure as a medium for designing the teacher evaluation system that they are focusing on. The presence of only 18% of studies relying on a specific theory reveals that policy makers need more evidence in order to turn their attention to appropriate directions for improvement of teacher evaluation systems. This argument is also supported, by the fact

that in the validation of evaluation systems category, the use of experimental studies (7%, $n = 8/121$) and longitudinal studies (7%, $n = 9/121$) were also very limited.

Lastly, it is important to note the lack of studies examining the aspect of meta-evaluation in an evaluation system. The absence of a meta-evaluation system is also emphasized in the previous section of this chapter. More specifically, in this meta-analysis, only 14 studies in the general set of studies (9%) were found to report on a meta-evaluation system. This finding can be attributed to the difficulty of the educational systems to change their evaluation mechanisms over time (Fitzpatrick et al., 2004; Scriven, 2009; Stufflebeam, 2011). In addition, this finding shows that the research community has not yet developed enough initiatives to explore the effectiveness of the existing teacher evaluation systems. Taking this into consideration, in the last section of this chapter below, we stress the significance of taking all aspects of a comprehensive teacher evaluation system described in this chapter, into account and we propose actions that could be initiated by the researchers in this field in order to establish links between research on teacher effectiveness and reform policies on teacher evaluation.

Conclusions

Teacher evaluation is considered a vital element for assuring teacher quality and for promoting not only the professional development of teachers but also students' learning outcomes (Seidel and Shavelson, 2007; Stronge, 2006b, 2007). In the first three sections of this chapter a literature review on teacher evaluation has given emphasis to four main aspects that need to be taken into account when developing a comprehensive and effective teacher evaluation system: (1) the evaluation purposes, (2) the evaluation criteria, (3) the sources for collecting relevant data and (4) the meta-evaluation mechanisms. We argued that a teacher evaluation system should be built on both purposes of evaluation (summative and formative), as it is important to give emphasis on both outcome and improvement. However, policy makers should be able to establish different mechanisms of formative and summative teacher evaluation, since the two purposes of evaluation are based on different value assumptions. Consequently, different criteria can be used for conducting each type of teacher evaluation. Thus, in the second section of the chapter we explicitly refer to seven TER models in developing criteria for teacher evaluation. There is a need for using TER to generate separate criteria for the two purposes of evaluation, since a certain group of criteria may be more appropriate for formative evaluation and a different (or at least different in some aspects) set of criteria may be more suitable for summative evaluation. Hence, we suggest the incorporation of multiple models of teacher evaluation, as different perspectives may generate a detailed outline of the teaching and learning situation/process. For example, focusing solely on the goal and task model, we may have evidence of effective and ineffective teachers, but there is no guidance of how teachers could improve their practices. On the other hand, focusing only on the working process model evaluators may distinguish what features of teaching could be improved by consequently setting up appropriate teacher professional development programs, but questions regarding to what standards are teachers evaluated and how are those standards related to students' progress, should also be raised. In addition, for each criterion that is judged important for developing a teacher evaluation system, appropriate sources of data upon which the measurement of teacher effectiveness could be based should be identified. Accordingly, combining multiple sources for measuring the quality of teaching, may reveal unseen aspects of teacher effectiveness and lead to specific actions for improvement. Moreover, specific instruments need to be developed to collect data from each source and their construct validity should be systematically investigated.

In the third section of the chapter the fourth aspect of a comprehensive teacher evaluation system is emphasized, since when designing such an evaluation system, monitoring is the key factor of the process for assuring quality of the desired outcomes. Meta-evaluation processes are reported only rarely in the related literature either due to the resistance of stakeholders participating in the design of a teacher evaluation process and providing accountability transparency or because the research community has not yet developed enough initiatives to explore the effectiveness of the existing teacher evaluation systems. We, thus, emphasize through the results of the descriptive analysis of the data of the meta-analysis reported in the fourth section of this chapter, that it is important for countries to design their own teacher evaluation system based on empirical data as well as on a valid theoretical framework. The existence of a theoretical framework is valuable when designing a teacher evaluation system since this framework will guide the decisions of policymakers as regards to the criteria that can be used for evaluating teachers as well as the sources of data that will be used.

The results of the meta-analysis reported in this chapter, showed an increasing interest of the research community on teacher evaluation, during the last 5 years. This is an important finding especially since an interest on teacher evaluation research was also observed in various developing countries. More specifically, some countries were found to introduce policies and practices that are currently used in other developed countries. This "borrowing policy" is found to be ineffective by the research community. There are matters concerning the relevance of the "borrowed policies" with each country's context and framework relating to teacher evaluation. It is also important to note that policymakers should not simply introduce reforms that are in line with the perceptions of various stakeholders, but only promote those reforms which were found to promote quality of teaching and student learning outcomes. Finally, most studies conducted in the field of teacher evaluation concern the investigation of the effectiveness of existing evaluation systems, rather than suggesting new approaches to teacher evaluation and testing their impact on improving teacher effectiveness and student learning outcomes. The research community is encouraged to search for effective approaches to teacher evaluation that are based on theories. Findings of these studies are more likely to be used by policymakers who are expected to develop comprehensive teacher evaluation reforms, which will not only be valid and reliable but should also have an effect on promoting quality and equity in education. We, therefore, argue for the use of a theory-driven and evidence-based approach to

generate teacher evaluation systems in each country which will cover the purposes of the evaluation, the evaluation criteria, the sources for collecting relevant data, as well as the meta-evaluation mechanisms for supporting the continuous improvement of teacher evaluation systems.

Leading school-based assessment for educational improvement: rethinking accountability

Globally, there is increasing pressure from politicians, public policy, and parents to know (1) that students in schools are learning what is expected and (2) that schools (i.e., leaders and teachers) are adding value to student learning (Buckendahl, 2016). The pressure comes from a valid concern about the importance of academic outcomes for student life chances (i.e., educationally successful students get better jobs, earn more, and have more fulfilling lives) and for societal development (i.e., our country and its economy will be better if more and more students are well educated). While some experts may reject the notion that schools should be held to account for their use of funding or practices (Biesta, 2010), that is not how most members of society see good educational practice. A simple view simply expects that teachers cause students to do better on valued and presumably accurate measures of learning (Harris and Brown, 2016).

Accountability pressure also arises from the unpalatable realization that not every teacher is as good as another (McNaughton and Lai, 2009) and that it is difficult to improve teachers (Richardson and Placier, 2001). For example, studies in New Zealand have shown that teachers make curriculum decisions independent of assessment information that would show what the student really needs (Parr and Timperley, 2008). Teachers' overall judgments of student capability in New Zealand have been shown to be biased against student standardized test performance scores for all students except white girls (Meissel et al., 2017). Hence, the quality and effectiveness of teachers is not universal.

Educational assessments are frequently used to demonstrate that individual students have fulfilled our expectations (e.g., tests and examinations for entry or qualifications) and test scores from surveys of school performance are used to identify schools and teachers who are associated with students whose performance meets societal expectations (Linn, 2000). The trend to use student tests (most commonly of reading comprehension and mathematics) to evaluate the quality of teachers and schools has become especially prevalent in the United States of America and England (Lingard and Lewis, 2016). In other jurisdictions where public examinations are commonplace (e.g., Asia, Africa, the Middle East; Brown, 2017; Gebril, 2016), the prestige of schools and teachers often depends on the success rate of their students on such high-stakes assessments. Hence, judging teachers and schools by the test performance of their students is both widespread, easy to achieve, and very influential on teachers and school leaders. After all, no school leader wants to be associated with what may be seen as "failure" in the face of its constituent communities (Ngan et al., 2010).

The problem with this pressure is that, teachers feel compelled to deliver exactly what those in authority want; that is, higher test scores. This is a natural human response to accountability pressure; subordinates deliver to those in authority whatever they consider it is that superiors want—the first consequence of accountability (Lerner and Tetlock, 1999). Putting aside whether or not teachers are doing a substandard job, we need to consider whether it is possible to raise test scores without any real learning taking place. Are there ways for teachers to meet the expectation that student test scores will go up, despite students not achieving the learning goals expected?

Unfortunately, the answer is yes. Scores can be increased by a number of means (Cannell, 1989):

- teaching students directly what will be on the test,
- using old tests that have invalid comparison norms,
- getting an early copy of the test and ensuring items are taught prior to the test,
- encouraging low performing students to NOT come to school on testing days,
- giving students hints during testing,
- correcting student test responses before submission to a central agency, and

- a plethora of such dubious acts.

In 2015, teachers and school leaders were jailed in Atlanta, USA for falsifying student performances on school accountability tests.¹ My sense is that in light of the unfair negative consequences (e.g., my school has many children whose parents are poor, uneducated; my school does not have resources; my school is in a location where it is difficult to attract highly skilled teachers; labeling kids as failures is wrong; or using standardized tests to determine a child's worth is wrong) for low scores, "cheating" to raise test scores may be a highly rational, albeit unprofessional, response. It seems highly likely under a regime of accountability, which ignores the many complicating factors that limit student test performance, resistance and subversion of the regime is likely and possibly defensible.

Constraints on accountability assessment

Leading with assessment data poses substantial challenges for teachers. Unfortunately, in many societies school leaders face a context in which they are driven to respond positively to accountability demands, that seem disconnected from circumstances outside the control of schools, leaders, and teachers. As demonstrated powerfully over and over, factors in the home resources of any child account for a large proportion (usually estimated at 50%) of school achievement (Coleman, 1966; Hattie, 2009). Hence, the imposition of negative and strong consequences for "poor" performance that does not take into account input factors outside the control of educators is inherently unfair (Nichols and Harris, 2016). Nonetheless, school leaders have to face those accountability demands and lead teachers to instructional practices that fulfill adequately those demands (Daniëls et al., 2019). In my view, two important conditions must be present if school leaders or teachers are to use address accountability demands transformationally.

Consequences for assessment

It is relatively clear that school systems have the choice to control the level of consequence they attach to school-based assessments. This decision will be in part determined by how policy makers conceive of the role education professionals play. If they view teachers as the problem, they will probably attempt to put into place teacher-proof curricula or impose a regime of consequences for low test scores (e.g., firing, redeployment, salary impact, etc.; Nichols and Harris, 2016). If they view teachers as professionals through whom policy is implemented and manifested, then a substantially more formative approach might be taken to accountability tests (Hattie et al., 2003). In a formative approach, consequences for low scores focus on support and resources for changing the factors that generated the results. Whatever the mindset for accountability testing, policy makers need to take into account the psychology of the agents through whom the policy is deployed.

The willing compliance and cooperation of teachers and school leaders is needed for any policy, not just assessment. This means that the beliefs and attitudes of school teachers matter to how school-based assessment reforms are implemented. There is strong evidence that teacher beliefs contribute to how teachers understand their work contexts, what they are supposed to do, and how they should do it (Fives and Buehl, 2012). Clearly, the meaning of assessment to teachers matters to how school-based assessment can be affected. Brown (2008) has argued that there are four major purposes of assessment (i.e., improved teaching & learning; evaluation of students; evaluation of schools & teachers; negative purposes). Evidence has accumulated that teacher beliefs about assessment depend in part upon the policy and cultural constraints in which teachers work (Barnes et al., 2015; Bonner, 2016; Fulmer et al., 2015).

Research in many countries has found that the relationship of improvement (generally endorsed by all) has an interesting tension with evaluation or accountability purposes (especially school evaluation). For example, school evaluation was weakly correlated with improvement in New Zealand (Brown, 2004, 2011), Queensland (Brown et al., 2011b), and Cyprus (Brown and Michaelides, 2011) all of which had low-stakes assessment environments in which schools and teachers were not punished for low test scores. It's interesting to note that in a New Zealand study (Brown, 2009a), primary school teachers associated student accountability with surface (memorization) learning, whereas school accountability was associated with deep (transformational) learning. This was understood to mean that the teachers thought good schools created deep learning which was not easily captured by standardized tests.

In contrast, improvement and accountability beliefs are strongly correlated in Hong Kong (Brown et al., 2009), China (Brown et al., 2011a), Egypt (Gebril and Brown, 2014), and India (Brown et al., 2015), all of which are high-stakes public examination environments, in which school and teacher quality are inferred from student test scores. Hence, understanding what accountability assessment does to schools and teachers depends on knowing what consequences or purposes are attached to the tests and their scores.

Contextual effects exist within societies where the age and stage of schooling changes. High school teachers tend to generally agree that student evaluation is an actual purpose for assessment by statistically significant margins over primary school teachers. This probably happens because qualifications assessments are a natural, normal, and expected part of schooling for adolescent children (Brown, 2011; Brown et al., 2011b). This indicates teachers are not unrealistic about the importance of ensuring students meet expectations for young people prior to entering work or higher education.

¹https://en.wikipedia.org/wiki/Atlanta_Public_Schools_cheating_scandal.

In societies where examinations are used to select students for limited resources (e.g., scholarship to university), such assessments are seen as both a way to make students accountable and simultaneously as a way to improve. In addition to improved academic performance through assessment, in China, it seems teachers associate greater academic achievement with greater acquisition of scholarly virtues as a better person, giving even greater impetus to the belief that assessment leads to improvement (Brown et al., 2009, 2011; Brown et al., 2011a). The downside to this perspective is simple; the outcomes of teaching depend not on the school leadership or teacher quality, but rather on the student. The practices of instruction do not need to change if student effort or virtue are responsible for outcomes. Hence, this perspective can lend itself to defending teachers from criticism and/or improvement.

Commitment to improvement depends upon both policy and leadership. National surveys carried out among New Zealand primary and secondary teachers under conditions of low-stakes school accountability mechanisms (i.e., tests were voluntary and inspections were triennial), teachers generally endorsed the notion that assessment was for improvement and not much for school evaluation (Brown, 2004, 2011). Subsequently, the Ministry of Education supported schools in adopting a schooling improvement initiative in which school leaders were to actively use school-wide achievement data to guide changes in curriculum and teaching. However, a survey of Auckland teachers in those schools indicated that assessment was much more irrelevant and much more for school accountability, than for improvement, than the previous national surveys (Brown and Harris, 2009). It seemed, when talking with teachers, that some were persuaded that educational assessment is about evaluating schools, rather than improving teaching and learning. If assessment was something for school leadership then it became legitimate to ignore or reject the assessment process.

Thus, making it safe to discover “bad” news (i.e., low scores) has to be real, otherwise teachers will treat assessments as a game in which the goal is to maximize scores. The environment in which assessment is deployed impacts teacher understanding of assessment practices; Saldaña and Shepard (2023) provide multiple examples of the impact of local context upon school use of test scores. Teacher beliefs about what assessment is and what it is for contribute to deep transformational improvement or surface compliance. Reducing external consequences in favor of internally-monitored professionalism is a powerful strategy to take advantage of teachers’ commitment to educational improvement. Nonetheless, as Bonner (2016) demonstrates the tension between meeting accountability demands and improvement goals places a substantial burden on educators. Lillejord (2023) provides further insights into policy frameworks that constructively support teachers in meeting this goal of improvement.

Assessment validity

In order to contribute to either or both formative and summative decision-making, assessments are expected to be both valid samples of valued domains and provide reliable, consistent, and truthful scores about performance (Messick, 1989). Accurate scoring of performance on a sample of items about competencies or capabilities is a feature of standardized, well-prepared tests. This contrasts considerably to the inconsistency in teacher judgements on performance assessments (e.g., essays; Brown, 2009b, 2010). Notwithstanding concerns about the validity of tests, they are relatively cheap, quick, and easy to develop and tend to provide the kinds of scores which easily satisfy politicians, media, and parents (Linn, 2000).

Nonetheless, a considerable problem with tests is the limited information provided through total or rank order scores (Brown and Hattie, 2012; Hattie and Brown, 2010). Standardized tests or examinations tend to produce information about the total score (i.e., percent correct score or letter grade) and information about how well students have done relative to normative samples (i.e., stanine, percentile, z-score, etc.). Total scores are not overly useful in schools because they do not identify which aspects of the domain a student is weak or strong in; neither do they identify which students have which learning needs in each important area. Rank order scores likewise have limited usefulness, since most teachers already know which students are at the top or bottom of their own classes (Elley and Livingstone, 1972). Teachers tend not to know how good their class is relative to the rest of the country population; this means a weak student in my class is seen as a weak student in the jurisdiction, even if the class is in a top performing school. While it is useful to know if a score differs a little or a lot compared to the norm, this does not tell teachers how to use that score to make a difference. Thus, tests that only provide total and rank scores fail to generate the information school leaders and teachers need to make systematic changes to instruction so that students learn more. Another trap with these kinds of statistical data lies in the relative inability of teachers to make proper sense of test scores, the illusion that such test scores are objective and correct, and the loss of details about individual learners in aggregation of scores into means (Fjørtoft and Lai, 2020).

To address this problem, rather than dispense with standardized tests altogether, in New Zealand, a standardized, school-based test system was developed to provide high-quality diagnostic and formative information to both teachers and school leaders (Brown, 2013; Hattie and Brown, 2008; Hattie et al., 2003, 2004). The Assessment Tools for Teaching and Learning (asTTle) computer-assisted software system (now a fully online web-based system) was developed to assist the teacher with two onerous tasks; that is, creating a test and analyzing student performance. The asTTle software uses a sophisticated linear programming heuristic to create both paper and computer-adaptive online test options using a mixture of open- and closed-response items to fit the teacher curriculum and difficulty requirements. Teachers determine the validity of the test, thus ensuring it fits their students and their teaching. The system software calculates student achievement, strengths, and weaknesses using an item response theory formula so that regardless of the items on a test, student scores are on a common scale. This ensures interpretation against nationally representative norms, curriculum levels, and curriculum achievement objectives.

Like other tests, the system provides nationally comparative rank-order scores and standardized total scores. Unlike other systems, it also reports the strengths and weaknesses of individuals and groups right down to learning objectives within the various strands of the curriculum for reading comprehension, writing, and mathematics (Brown et al., 2018). Additionally, it points

teachers to high-quality curriculum resources to support better teaching of all students regardless of whether they are behind or ahead of expectations. Further, since the system is designed to be formative, the stakes or consequences are generally low because schools see and respond to the information before external authorities. This allows improvement to take place before external accountability inspections take place and helps to show the competence of educational professionals. This model of assessment has the potential to enable school leadership for improved outcomes as the priority for educational assessment.

Leading for learning

It is thus necessary for school leaders to resist the temptation to inflate test scores through devious means. It also means that the environment of consequence and test resources has to be in place for leaders to turn assessment into an educational practice. Real, transformational learning is not a simple input-output factory-like process; rather it is a complex set of interactions between students and insightful, enthusiastic, skilled educators over a long period of time. In essence, instructional leadership around the challenges of assessment for accountability require that:

Leaders who take into account and test the theories of those who are responsible for improvements are more likely to better understand the problem that they are trying to solve, better able to develop solutions that are accepted, and more likely to effect changes in the practices that they wish to impact. [Wilson and Lai \(2019, p. 458\)](#).

The school leader is responsible for leading instruction not just ensuring administrative compliance with accountability pressures. The real goal of school leadership is improved learning and instruction. To achieve this, school leaders need to adopt instructional leadership practices that research has shown lead to greater learning outcomes for students. [Daniëls et al. \(2019\)](#) demonstrate that instructional leadership frameworks now sit comfortably within the more recent Leadership for Learning framework, which focuses on learning, teaching, curricula, and instruction as well as ensuring all the other dimensions of schooling (e.g. administration, organization, finance) contribute to improved student learning. Nonetheless, the impact of school leadership on student learning outcomes is largely indirect as it depends on the subordinate middle managers and teachers implementing the learning vision of the leader.

In her synthesis of leadership practices that impact student learning outcomes, [Robinson \(2007\)](#) has shown that the most powerful effects on student learning are associated with leaders who: (1) promote and participate in teacher learning; (2) plan, coordinate, and evaluate teaching; (3) establish goals and expectations; (4) deal with strategic resourcing; and (5) provide an orderly and supportive environment. This list makes it clear that administrative competence is necessary but not sufficient. The meta-analysis showed that the largest gains occurred when school leaders were actively involved with their teachers in collecting and evaluating assessment data and in designing and monitoring pedagogical responses to the assessment results. This result is consistent with Hattie's meta-synthesis (2009) of effective practices that lead to greater student learning; teachers who use assessment data to inform them about their impact on student learning generate large educational gains ($d = 0.90$).

Fig. 1 Basic professional learning inquiry and knowledge building cycles. Adapted from [Timperley \(2011c\)](#).

Based on these findings a comprehensive, general model (Timperley, 2011b) of five sequential steps has been developed (Fig. 1). This has been modified for this chapter to highlight the role assessment data play in the process. Assessment data, alongside curricular objectives, provide insights into the knowledge and skills students need so as to be successful in learning in any domain. To exploit these data leaders and teachers need to jointly review the data to identify strengths and deficiencies in the student performance (Parr and Timperley, 2008; Timperley, 2005). One of the side effects of this approach is that educators may be surprised by what students can actually do, despite their perceptions.

Then, an analysis of the professional learning needs of the teachers is conducted; it may well be that teachers know the students need “x,” but teachers may not know how to deliver “x,” without replicating their previous practices. This is critical since we cannot assume that teachers’ competencies include the skills needed to meet the gaps identified; after all, if they already had the skills to teach “x,” why do the students still need to learn “x”? This approach is based on evidence that teacher expectations and pedagogical skills can limit children’s educational achievement (Timperley and Phillips, 2003; Parr and Timperley, 2008).

Leaders must then take action to understand the professional development needs of teachers and take action to ensure that those resources are available. A key component of this stage is the active involvement of the various leaders; teachers will not take seriously this reform or change. If teachers see that the leader is not actively committed to the change and supporting them in adopting the change, then it is unlikely teachers will lead. Leaders who retreat to their offices to carry on administration are not acting as instructional leaders.

As and after the planned changes are implemented, assessment of impact on students is needed. Using an action research outlook (Robinson and Lai, 2006), this approach takes a tentative view of the efficacy of the changes on the basis that the theory underlying the analysis may be mistaken. It is easy to misunderstand the problem, to misdiagnose the causes, to mismeasure the domain, or ineffectively implement the change. Assessment data here may reveal new insights into the problem, suggesting further modifications to the solution. Having seen (or not) impact of the professional development on student learning, the assessment data are used to identify next steps in what students need next. It is important to monitor teacher practices to ensure that they do not slip back into old ineffective practices; continued assessment data can help identify reduced impact on student learning.

New Zealand research

Effective leadership in times of accountability will depend on the context in which schools and leaders are situated (Daniëls et al., 2019). So how are school leaders using educational assessment in New Zealand and does it really lead to improved student outcomes? It is worth noting first that the “approach to assessment, for example, allows for an emphasis on collaborative analysis of achievement data and a relentless focus on achievement using a range of assessments without the ‘baggage’ of high stakes assessment” (Lai et al., 2020, p. 35).

New Zealand has a somewhat unique assessment environment, that helps school leaders meet accountability demands in accordance with Leading for Learning principles. The *New Zealand Government* (2011, p. 9) stated that “In New Zealand, there is a deliberate focus on the use of professional teacher judgment underpinned by *assessment for learning* principles rather than a narrow testing regime.” The national assessment policy prior to Year 11 (students nominally 15 years old) emphasizes voluntary, school-based assessment for the purposes of raising achievement and improving instruction relative to the outcomes and objectives specified in the national curriculum (Crooks, 2010). New Zealand has standardized diagnostic tests that are aimed at informing improved teaching, a reliance on teachers’ judgment about learning, and a culture of collaboration within and between schools (Lai et al., 2020).

These affordances mean that leaders can treat assessment data as one part of the data profile of a school setting, allowing them to collaboratively understand why results are as they are, and experiment with solutions that are likely to redress learning outcome challenges. All of this can take place with little fear of being seen as a “bad” school because school accountability testing is not a practice in the environment. Furthermore, given that external school evaluations are carried out by the Education Review Office (ERO) through triennial site visits and school self-evaluations, the need for school accountability testing has been eschewed. The ERO does not require that schools demonstrate effectiveness with any one assessment method, but rather allows them to select from a range of assessment methods to demonstrate schooling effectiveness.

Research into improving outcomes in schools has relied on a number of support factors. Partnerships between schools and university researchers receive substantial funding from government. Interventions focus on improving teacher capabilities in response to robust diagnostic, formative assessment data. School and subject leaders were actively involved in analysis, interpretation, design, and monitoring of professional development activities. Substantial time for teacher changes to become visible on student learning performance were given. Under these conditions, evidence that leadership makes a difference is found.

Timperley (2005) found small but statistically significant effects ($d \approx 0.20$) in an 18-month action research study involving teachers and a school leader in learning to use assessment data to guide reading instruction. Government funded professional development projects in reading and writing have involved more than 300 schools and nearly 4000 teachers in 2–3 year-long school development studies (Parr et al., 2007; Sīlata et al., 2011; Timperley et al., 2010). These studies consistently show that after 2–3 years of professional development student learning in reading and writing gained more than national norms (observed changes in student learning were above national norm gains by between 0.50 and 2.50 times) and greater gains were seen among the lowest achieving students. However, not all school data analysis projects produce such large learning gains.

The more important changes lie in how data are used by leaders and teachers together. The Learning Schools Model (LSM; Lai and McNaughton, 2016; Lai and Schildkamp, 2016; McNaughton et al., 2012) involves school leaders and teachers working with professional researchers. The model involves creating baseline profiles and collaborative analysis of data, a series of workshops focused on analysis of data, and design and monitoring of interventions that should redress problems identified at the start. LSM has been implemented in schools with high proportions of low achieving students and contributed to increased student learning of about 3–4 months additional progress per year. While the gains are sustained and large, even after 3 years, they did not result in these below average students reaching the national norms. Large effects in student literacy were found in a 3-year longitudinal LSM study (Lai et al., 2009). In this study, learning gains were initially small, but showed evidence of acceleration over time suggesting persistence in the intervention process is required to bring about sustained change in teaching and learning. Furthermore, the changes were sustained because they became part of normal school routines for conducting organizational inquiry focused on solving teaching and learning problems through professional learning communities (Lai et al., 2009). Part of what makes the changes sustainable is that they are for the most part small modifications to existing practices (McNaughton and Lai, 2009); schools already (1) assess students, (2) plan teaching, (3) modify teaching, and (4) evaluate performance.

What is different throughout these interventions is the joint participation of the school leader with the teachers and a focus on student learning. The quality of the principal's involvement in these changes is critical; a study of five schools (Timperley, 2011a) in which there was exceptionally high learning gains revealed that the teachers considered their leader had scored 5 or 6 out of 6 for each of the five instructional leadership strategies identified by Robinson (2007), with the principals themselves emphasizing the function of promoting and participating in teacher learning and development. This really meant that the leaders not only had high levels of content and pedagogical knowledge, but they also led teachers into learning and implementing both kinds of knowledge (Timperley, 2011a). Hence, if the school leader lacks confidence or competence to act as a learning leader, changes around assessment practices or data use will be insufficient.

Conclusion

The challenge for school leaders is substantial. Leaders must not just manage and administer schools. If learning is to happen they must be competent in analyzing data and leading their teachers into changed classroom practices which are based on and evaluated with achievement data. Further, leaders must have deep expert knowledge in the content areas being considered; this of course requires distributed leadership through teams of leaders with expertise in relevant and complementary domains. Additionally, leaders must understand how teachers think about accountability pressures and be adept at raising professional thinking about the use of assessment data, while avoiding score inflation for the sake of conforming to accountability expectations. Many school leaders may be reluctant to initiate such action for fear of punitive responses from the political system. Hence, the challenge is also for government policy makers and inspection or evaluation officials to ensure that it is safe for schools to discover bad news about student learning. Under fear of consequences, the honesty to know and grapple with problems in teaching or leadership practices is unlikely. The New Zealand research especially shows that university researchers need to participate with schools to introduce new theories, new instructional techniques, and robust data analysis methods. Without combined efforts and resources, it is unlikely accountability assessment will achieve more than compliance—higher scores without deeper or richer learning outcomes. A significant challenge exists, but there are promising results from New Zealand, under contexts that are highly conducive to success, that school leaders, who use assessment for learning with their teaching staff in the ways described here, contribute to real learning gains.

Acknowledgment

I wish to thank my colleagues at the University of Auckland who helped me understand the methods and progress they had made in helping school leaders make a difference to staff and student learning. Specifically, thanks go to Dr. Brian Annan, Assoc. Prof. Mei Kuin Lai, Prof. Stuart McNaughton, Prof. Judy Parr, and Prof. Helen Timperley.

Introduction

Many discussions of accountability start by attempting its definition, and most conclude that there are many types—for example, professional accountability, bureaucratic accountability and market-based or technical-managerial accountability (Barbana et al., 2020; Grek et al., 2021). These different definitions illuminate the need to approach accountability from a perspective that is attentive to the social and political conditions within which the term is being employed, the actors employing it, and the contexts within which they operate. Such a framework necessarily connects changes in accountability to changes in governance, in education and beyond. This discussion draws on research on education primarily, but not exclusively, focusing on Europe, which explores knowledge-governing relations and highlights the knowledge-based resources available to transnational governing elites, including regulatory instruments and performance data (see for example, Grek, 2009; Ozga et al., 2011; Lawn and Grek, 2012; Fenwick et al., 2014; Verger et al., 2019). It shows how those instruments make possible the shift toward governing through networks of new actors, often located in International Organizations (IOs) who define education in global terms, prioritize the redefinition of education as learning, and mobilize the application of policy “solutions” derived from benchmarking, indicators and performance measurement across nation-states. (Gorur, 2017; Waldow and Steiner-Khamsi, 2019).

Accountability, then, is placed here within the context of neo-liberal globalization, that drives the economizing of education, and the promotion of competition as the lever that produces improved performance. In tandem, new public management (NPM) installs monitoring and performance management systems, while the growth of technical capacity enables the collection, analysis and distribution of unprecedented amounts of performance data, and supports the production of benchmarks, indicators and rankings, which together constitute a dominant way of seeing and thus governing, education. The more recent growth in complexity of data creates a space for expert “translators” and mediators, especially those based in or connected with IOs, as well as those in private companies, to take active roles in governing, and to promote as “natural” (Novoa and Yariv-Mashal, 2003) evidence-based solutions to educational problems. Raising attainment levels and connecting this drive to increased economic performance become the dominant drivers of education policy and create pressures for standardization and comparison, including through the promotion of test-based accountabilities. These developments are highly interdependent and are discussed below.

Drivers of TBA: globalization, NPM, data

Neo-liberal globalization drives the integration of markets worldwide (Bishop and Payne, 2021) and erodes the distinction between states and markets. It brings about changes in the architecture of power globally and within nation-states, privileging the market and enhancing the power of economic institutions, such as multi-nationals, and other IOs. It can thus be understood as the overarching context in relation to changing governing, while the associated agenda of knowledge economy-driven change installs competition and suppresses historically embedded shared values and practices that have informed national education provision, including in relation to accountability. Neo-liberal globalization has shaped and is shaping a global structured agenda for education (Robertson and Dale, 2017), as broadly similar education “reform” programs are implemented in widely varying settings (Sahlberg, 2016).

As the measurement and comparison of learning outcomes is understood to be central to establishing and improving levels of economic competitiveness globally (Verger et al., 2019), educational processes are collapsed into outcomes, especially demonstrable and quantifiable learning outcomes. All forms of education, from early childhood provision, through schools, vocational education and training, and higher education are interconnected through the attitudes and dispositions encouraged by new learning agendas and practices, including international testing, which claim consistency across populations, institutions and national contexts. Schooling and post-school education is focused on developing learners’ capacity to learn, while learners also learn to constantly evaluate their learning through self-evaluation, and through the use of international performance testing that produces comparative data from which systems supposedly learn how to improve (Addey et al., 2017; Falabella, 2021; Grek, 2013).

Globalization thus erodes state responsibility and state capacity for service provision. The dispersion of state responsibilities produced by the combined effects of neo-liberal ideology and NPM principles weakens the responsibility of national politicians for key areas of public policy and disrupts traditional lines of accountability. These lines of accountability were designed—in

principle, if not always in practice—to enable the effective communication of decisions, to respond to the expression of public feeling, and to sustain policy-makers' claims to legitimate authority. The privatization and decentralization that accompanied the implementation of New Public Management (NPM), combined with simultaneous decentralization and re-centralization of government functions, obscures and complicates accountability, making it hard to see clearly who is accountable for what. Direct lines of political accountability from governments to the electorate and through elected local representatives with responsibility for provision are reduced or obscured. Instead, technical-managerial accountability operates to ensure that, through the publication of data across a range of locales—from individual learners, teachers, institutions, municipalities and national governments, citizens, redefined as stakeholders, can see and judge performance, and make choices informed by this evidence. In this form, as Newman and Clarke suggest, accountability has been adopted internationally as part of the conception of information or evidence-based “good governance” in which transparency, participation and performance are apparently combined (see Newman and Clarke, 2009: 100–102).

In Europe, it is possible to trace a shift, to a greater or lesser degree, from professional accountability to what Ranson (2003) calls neo-liberal corporate accountability, and then-again, in differing degrees-towards test-based accountability. That transition expressed movement from the hierarchical practices of public sector bureaucracies in which accountability “upwards” involved teachers being accountable to parents, to the local authority/municipality, to governing boards, while local and national politicians were “downwards” accountable to their electorates. These forms of accountability involved exchanges of “accounts,” that is, narratives that conveyed meaning about values in contexts of multiple and reciprocal answer abilities, and which could differ, that is they could involve conflicts of purpose in different contexts (Ranson, 2003: 461). It should be stressed that these narratives are not without problems, and it is recognized that the outcomes of conflicts of purpose within that system tended to favor the more powerful. However, the point is that spaces for debate and conflict about priorities, purposes and values in the provision of education existed, at least acknowledging the contested politics and power relations that are an inherent feature of education policy (Ozga, 2020).

From the 1980s onwards, especially in the Anglosphere, policy makers adopted the practices and assumptions of NPM and so redefined accountability as the management and scrutiny of performance at all levels—from the international competition of league table positioning though to the constant review of performance against hard and soft targets that is installed in teachers and pupils through forms of self-evaluation. More recently, test based accountability is acknowledged as spreading internationally (Addey et al., 2017; Barbana et al., 2020) throughout continental Europe, including the Nordic countries (Camphuijsen et al., 2020; Mau-Sethagen, 2013) and globally, in the USA, in Australia, Canada and Latin America. As well as the ideological dominance of neo-liberalism it is important, in accounting for the international take up of this version of accountability, albeit at different speeds and to different degrees, to note the increased capacity and use of data in education as in other fields, and the contribution that data growth and development make to TBA. Data enter the frame because the transmission of information is necessary to hold together the diverse and networked governing forms that accompany globalization. Data enable this complex education arena to be calculated, for example through the Bologna Accord, that harmonizes different European higher education systems by creating a single degree system and the Lisbon Process or Open Method of Coordination (OMC) in which benchmarking and comparison are core governing processes across a “learning society” shaped by economic reform, citizenship obligations, employability and international comparison and performance testing in education (Grek et al., 2021).

Local government and schools are now rendered visible and calculable (Ozga et al., 2011). Data expressed as public rankings, league tables and international test results enable and consolidate control over a wide network of actors and institutions—national governments, local authorities, schools and teachers included. The construction of indicators and the collection and processing of performance data install comparison as a basic principle in building policy consensus and also, importantly, in embedding self-regulation (Ozga et al., 2011; Grek, 2014) as data systems not only monitor the activity of teachers and learners, but also shape individual conduct while apparently enabling autonomous, choice-making activity supported by information (Piattoeva, 2014). Throughout the countries in the various research projects on which this paper draws, there is a growth in knowledge/information expressed in quantitative forms, through comparative statistics, charts, diagrams and comparative tables, competency-based curricula and pedagogy that is partly driven by measurements of competence. There is a stronger emphasis on the production of knowledge about performance in quantitative forms that can be shared, analyzed and translated into benchmarks and indicators. There is a growth of evaluation, accompanied by “scientisation.” Accountability is clearly linked to the production and circulation of data-based knowledge and is linked to introducing self-regulation (of teachers and pupils). There is increasing emphasis on technical, “objective” knowledge as the basis for evaluation of performance by external agencies and internal audiences alike.

These different developments together change the way in which education is understood and visualized: data enable schools and education systems to be seen as “computational” projects (Selwyn, 2018) and the “modeling” of education through digital data creates algorithmically driven “systems thinking” where complex social problems are converted into complex but apparently solvable statistical problems. Thus, digital data encourage “solutionism” and suppress debate and discussion about the purposes and content of education, or about different assessment forms, while the space available for political conflict or contention about priorities, purposes and process is effectively shut down. In this way data use produces education settings (Selwyn, 2018). Put differently, data and data practices are not neutral representations or measurements of educational activities, but ways of establishing these practices as defining features of education.

Digital data work within education/schooling is now normalized—it is understood almost universally as the basis of improvement, and it is increasing in scope, including in Higher education, where multi-nationals see market opportunities. From this perspective, the very significant development of data resources in education from the early 2000s is not only a story of increased

technical capacity but connects directly to the prioritization and spread of test-based assessments. Furthermore, data enable the growth of networks engaged in governing work, often through IOs or transnational organizations, whose influence is discussed below.

International organizations

The combined effects of neo-liberal globalization, new public management and the growth and increased sophistication of data systems together enable international organizations (IOs) such as the OECD, the World Bank or the European Commission, or private, corporate actors such as McKinsey or Pearson, to occupy a key space in the governing of education. The global governance of education is increasingly organized through multi-layered international networks of collaboration linking national and local actors to worldwide networks and structures, with the capacity for global political action.

The term “governance” rather than government is used by many contemporary scholars to draw attention to the growing diversity of actors and organizational forms engaged in governance work, including in education. The term indicates a changed landscape: one in which the traditional models of government, understood as restricted to specific, legally-recognized functions and levels within the nation-state, no longer apply. Governance implies acceptance of a shift away from fixed and bordered institutions, from stable bureaucratic forms and hierarchies toward the flexible and adaptive modes of co-ordination of markets and networks (Ozga, 2019) and may also imply a decline in the influence and capacity of the state. Indeed the shift to governance follows logically from the increased complexity of service provision, as the traditional state form became more and more differentiated to meet more complex demands. Networks then emerge as the natural form for the coordination and management of activity across different sectors (see, e.g., Ball et al., 2016; Shiroma, 2014), and the state becomes one actor among many.

These networks are engaged in what has been called “epistemic governance” that reflects the contemporary interdependency of governing and comparative, data-based knowledge (Alasuutari, 2016; Normand, 2016). The growth of this form of expertise is recognized as a transnational phenomenon, with experts increasingly working between national and transnational arenas, and identified as a “new governing elite” (Stone, 2013: 41, 2019) and a new “European technocracy” (Normand, 2016: 129), located in IOs. These IOs draw on the authority of science and expertise to promote their agendas and that politicization of science weakens its claims to independence. The knowledge distilled from test-based assessments supposedly enables IOs to engage in policy “teaching,” extracting from data about comparative performance lessons which enable systems to improve the quality of education provision and move their systems in productive, evidence-based policy directions. As indicated earlier, these agendas are highly dependent on growth of data use and capacity-in education and across public sector service provision. Data and data systems construct policy problems and frame policy solutions beyond and across the national scale. Epistemic governance moves more freely, uses more artifacts, and involves new actors in its production. The knowledge that is valued in governing is “actionable” (Grundmann and Stehr, 2012): that is, it contains advice about the direction to be taken. The massive expansion of information requires particular skills in simplifying, synthesizing and brokering to reduce possibilities and make knowledge actionable:

The rapid growth of experts, advisers and consultants in education arises from the rapid expansion of knowledge/information, this provides opportunities for simplification of the problem of endless competing interpretation in order to provide a basis for action.

Grundmann and Stehr (2012: 20–21).

This network of experts operates to produce and disseminate a “cognitive consensus” (Grundmann and Stehr, 2012) that is, a system of standardized policy agendas and their repertoire of benchmarks, indicators and competitive testing regimes. The homogeneity of programs of whole system structural education reform (Sahlberg, 2016) is striking, and this consensus is promoted through appeals to its “evidence based” nature, or its “common sense” about “what works” which conceals the political nature of translation, because, as Shiroma (2014) points out, the label “expert” confers scientific status and authority and seems to be above politics. The work that policy actors do in networks, whether as “chosen” experts, mediators and translators for OECD, or in private consultancy, strengthens the trend toward comparison and the search for trends and patterns in comparative data, and also increases the influence of analysts who can interpret data and turn it into policy advice (Grundmann and Stehr, 2012: 20–21).

The OECD's PISA and beyond

The Organization for Economic Co-operation and development (OECD) provides a paradigmatic case study of the increasing transnational influence of IOs in promoting standardized policies in education globally, and in using test-based accountability to sustain this governing activity. The OECD is able to present itself as an expert knowledge-based organization, “above” national politics, and sufficiently distanced from national contexts to be dispassionate and objective (Rautalin et al., 2021). The most visible manifestation of OECD's influence is the Program for International Student Assessment (PISA) first implemented in 2000. PISA measures students' knowledge and skills in three main domains: reading, scientific, and mathematical literacy as well as problem-solving capacity and financial literacy. PISA was redeveloped in 2012 into PISA for Development (PISA-D) with the aim of making the

instruments more relevant to low- and middle-income countries, a shift that also illustrated an expansion from simple data provision to stronger steering that seeks to change local cultures of assessment (Hopfenbeck et al., 2017). These assessments are decontextualized: that is, they are not concerned with national curricula and their success in promoting learning, but only with cross-national comparisons of levels of skill.

More recently, PISA has been further developed into the PISA Global Competence (PGC) program of assessment, which claims to measure:

'students' capacity to examine local, global and intercultural issues, to engage in open, appropriate and effective interactions with people from different cultures, and to act for collective well-being and sustainable development.

OECD (2018).

OECD's move into global competences, suggests, as Sellar (2015: 425, quoted in Engel et al., 2019) argues, that the organization is seeking to capture a broader range of skills and capacities that are presented as measurable globally and as "free" of cultural shaping or influences. By making competence a core concern of education systems, OECD ensures its continuing dominance in assessing progress in education, and by changing the basis of measurement, enables its even wider spread.

Global Competence is defined as "a multi-dimensional construct that requires a combination of knowledge, skills, attitudes and values successfully applied to global issues or intercultural situations" (OECD, 2018). This "multi-dimensional construct" was developed by experts who designed it to capture capacities that are understood to be measurable and assessable globally. As Gardinier (2020: 8–9) demonstrates, the measurement of global competence promotes an idea of global learners as "autonomous individuals who can separate themselves from their social identities." The imagined ideal learner is "future oriented, socially-mature, goal oriented, and extremely self-aware" (*op. cit.*: 9–10).

OECD describes global competence as follows:

"Global competence can help young people:

- develop cultural awareness and respectful interactions in increasingly diverse societies;
- recognize and challenge cultural biases and stereotypes, and facilitate harmonious living in multicultural communities;
- prepare for the world of work, which increasingly demands individuals who are effective communicators, are open to people from different cultural backgrounds, can build trust in diverse teams and can demonstrate respect for others, especially as technology continues to make it easier to connect on a global scale;
- capitalize on inherently interconnected digital spaces, question biased media representations, and express their voice responsibly online;
- care about global issues and engage in tackling social, political, economic and environmental challenges.

Global competence thus supports the Sustainable Development Goals (SDGs) both by providing the vision of education the SDGs advocate for, and by encouraging young people to act in the general interest of collective-wellbeing and sustainable development that the SDGs embody" (OECD, 2018).

This form of assessment, that seamlessly blends quite divergent and contested issues reflecting substantial social, political and economic problems, very clearly reflects concerns to manage problematic issues in global governance, problems that have arisen because of the exclusive focus on the economy, for example, increasing racism, unemployment and environmental damage. However, PGC places the responsibility for responding to these issues on individual learners, who must demonstrate their competence in "harmonious living," labor market readiness and environmental awareness.

OECD's description of PGC implies that there is "global consensus" on global competence and that experts have simply expressed this "cognitive consensus" and produced an assessment that countries can use to measure this concept. Yet it is apparent that PGC contains conflicting rationales and as Engel et al. (2019) point out, there is no consensus about who is imagined to be and gets the opportunity to become a globally competent citizen." Indeed, the promotion of the idea of consensus enables PGC to be shaped in ways that "may exclude orientations that do not fit the profile and values of the Northern/Western national citizen" (Engel et al., 2019: 125).

Concerns about the global applicability and comparability of the constructs that shape PISA in all its forms have long been expressed, and there is also an important literature on technical and conceptual issues with the design of PISA for schools (see, e.g., Baird et al., 2017). Furthermore, researchers have questioned whether there is, in fact, persuasive evidence that PISA and test-based accountability policies in general do improve the quality and efficiency of public education, while also highlighting the evidence that increased high-stakes testing is restricting students' conceptual learning, and damaging their understanding of creative action and innovation (Sahlberg, 2016).

PISA as a governing instrument is best understood as the direct product of the combination of the economization of education, the spread of NPM principles, and the influence of data systems and data-based expertise. The comparative basis of PISA enables participants to demonstrate globally and to their national publics that they embrace the modernizing logic of competition and reliance on evidence, it locates countries in the worldwide competitive space, identifies their relative positioning in the knowledge economy and holds out the promise of learning from the example of more successful competitors. Indeed, PISA has been shown to be a very powerful policy instrument that is able to penetrate different kinds of policy-making regimes and very diverse political

circumstances, because of its promotion as the “gold standard” of performance assessment, and because of its apparent adaptability to many disparate political ends. Carvahlo (2012) identified three modes of PISA knowledge use (i) as a basis for knowledge-based analyses of specific issues on the policy agenda; (ii) as a source for studies of national education “problems”; and (iii) as a resource for improving domestic regulation tools—in particular accountability mechanisms and quality assurance policies. PISA knowledge was mobilized to support the legitimacy of specific education policies within a broad policy framework, promoted by the European Commission, of enhanced economic competitiveness, as other commentators have noted (Lawn and Grek, 2012:104–105).

These are highly performative forms of accountability: policy makers are acutely conscious of the need to be seen to succeed both within the setting of the transnational construction of PISA and by their national media in relation to PISA outcomes. The OECD’s diagnosis of underperformance is accepted as the key problem that needs to be tackled through competition driven by the monitoring of the relative positioning of nations, schools, teachers and pupils. Policy makers are not rendered accountable to their electorates for poor performance as judged by PISA, rather they use PISA to justify policy directions that they had already sought to implement in their own contexts, especially where these data enable stronger measures of deregulation and privatization. Accountability is subsumed by visibility: where poor performance is acknowledged by a national policy maker it is attributed to poor teacher performance and not to national policy.

The nation-states participating in PISA and studied in research on its early implementation and effects were found to engage actively with this regulatory instrument despite the threat that PISA may pose to the nation-state’s capacity to act independently in the governing of its education system. This engagement requires the building of consensus about how problems are translated into national contexts through the creation of consensus and the incorporation and dissemination of ways of thinking and acting that draw policy makers into monitoring and mutual surveillance of education systems—practices that define their new identities and roles as system managers, operating within a technical-managerial form of accountability. PISA texts enable policy-makers to underline the rationality and scientific basis of their actions; to embrace modernization agendas that break away from national traditions, and to see their system’s performance in comparative terms within a European and global competitive space (Ozga et al., 2011). More recent scholarship, focusing on newer participants, suggests that participation may contribute to nation-building to access to political, economic or trade entities (Addey et al., 2017; Hopfenbeck et al., 2017); or is due to pressure to participate as signatories of global commitments. At the same time, PISA creates a space of discussion and brokering in which national and transnational experts and policy makers to interact in ways that allow nation states to be seen and to see themselves as independent and voluntary participants (Waldow and Steiner-Khamsi, 2019) while encouraging “best practice” and policy learning that enables national adaptation of the OECD “script.”

Indeed that “continuous crafting of its relationship with key education actors in other IOs and within national contexts” is a key element in explaining the continuous and growing influence of OECD (Grek, 2017: 298), and the interaction of local, national and international actors in “iterative processes of collective learning” is key to OECD’s achievement of a paradigm shift in the thinking and framing of education. The influence of global networks of experts is further apparent in the growing use and impact of Country Reviews (see, for example, Grek, 2013, 2017; Browes and Verger, 2020). PISA data first identifies “problems” that need to be addressed, and those problems may then be further investigated and remedies proposed through OECD’s process of Country Review, in which international teams of experts are invited by national governments to work with “local” experts to gather and analyze data to highlight issues at the national level, and then to provide advice and tools judged necessary to put things right. For example, Scotland has engaged substantially with OECD, following poor performance in PISA for schools 2015, where scores for maths, reading and science all declined. The Scottish Government commissioned OECD expert reviews (OECD, 2015) as well as appointing an International Council of Education Advisers, which together called for intensive reform processes that signaled disruptions and departures from established relationships between expertise, knowledge and policy. These required substantial system restructuring, increased concentration on attainment measures and stronger assessment and testing regimes. Media reporting of the PISA “crisis” fueled criticism of the teaching profession and encouraged an attempted policy shift toward the closer alignment of Scottish education with OECD’s norms (Ozga, 2021).

Research has identified different kinds of responses to the PISA results and very different effects on national policies (Waldow and Steiner-Khamsi, 2019; Grek et al., 2021). Research in Europe shows that in some spaces PISA results are suppressed while in others they become part of a triennial ephemeral spectacle (Grek, 2009). However, PISA’s significance in relation to the widespread equation of accountability with international test-based assessments is unquestioned; the literature illustrates its significance as a policy instrument that builds consensus through comparison, ordering and meaning-making within the framework of accountability understood as performance-based reporting. PISA draws its power from the combined effects of globalization, NPM and data, enabling policy to use comparative data to legitimizing preferred national policies on the basis of “international measures.” However what counts is not just the prevalence of comparison, but its use as the basis for:

the circulation of languages that tend to impose as ‘evident’ and ‘natural’ specific solutions for educational problems.

Novoa and Yariv-Mashal (2003).

Here Novoa and Yariv-Mashal highlight one of the key consequences of international comparison, and especially international performance testing: the centrality of competition to this mode of governance, and the push toward standardization through the elimination of alternative conceptualizations of what the key issues, problems or solutions in education might be. The example

of the assessment of global competence illustrates this well. The necessity of improving performance to meet economic need, and the assumption of improvement through competitive testing and ranking become “natural” orthodoxies that cannot be challenged. They further suggest that the continuous collection, production and publication of surveys of attainment create an “international spectacle” that replaces political debate; they identify a “logic of comparison” working through policy exchange, transfer and agreements to construct “a common understanding of ‘best practices’, leading to standardization of policy in Europe and beyond. They point out that the protected status of education in Europe as a sphere of national policy making through the principle of subsidiarity does not impede this process, as the European Commission’s construction of indicators serves as a “reference point” that eventually leads the various national institutions to adopt “freely” very similar actions and perspectives within the educational field. Novoa and Yariv-Mashal conclude that:

This new approach to European affairs reveals, clearly, a strategy to move the discussion away from matters of government (habited by citizens, elections, representation, etc.) and place it in the more diffused level of governance (habited by networks, peer review, agreements, etc.).
Novoa and Yariv-Mashal (2003).

Here Novoa and Yariv-Mashal capture key elements in the argument made in this piece about understanding international assessments as instruments for the governing of education, expressing as they do the combined force of change driven by neo-liberal globalization, by new public management practices, the growth of data and technical capacity, and the increasing influence of international organizations and the experts who work with them. These together function to exclude or conceal politics, and to erode and suppress spaces of debate and contestation around alternatives to the cognitive consensus.

Introduction

It is generally accepted that the world is experiencing a transition from an industrial age based on mechanization to an information age based on computerization (Autor et al., 2003; Autor and Price, 2013; Levy and Murnane, 2004, 2013; Reich, 1992; United Nations Conference on Trade and Development, 2017). The reach of computerization is extensive, affecting all aspects of life and work through the development of information and communication technologies (ICTs), replacing many existing human activities, and setting a premium on new competencies (Ananiadou and Claro, 2009; Deming, 2017; Gordon et al., 2009; Joyes et al., 2019; Lake, 2019; Levy and Murnane, 2004; Suto, 2013). This transition requires a reframing of educational aims for the information age, and these are typically represented as 21st century, key or core competencies, covering a range of knowledge, understandings, capabilities, skills and attributes.

Here, “competencies” is preferred to “competences”, though both are in common use and appear to have the same meaning (though “competency” and “competence” would appear to differ). There is also widespread reference to “21st century skills”, though skill would seem to be a narrower concept than competency, and not always applicable

Assessment needs to accommodate these reframed educational aims. Assessment, both in the classroom and for accountability, is recognized as a driver of what is learned and as a signifier of what is valued in learning. Haertel (2013) refers to these as incentive effects and messaging effects. That is, assessment focusses effort on the targeted learning outcomes and it also shapes perceptions of what learning is important and worth attention. The narrowness and shallowness of much educational testing is therefore problematic. Attention to 21st century competencies indicates an emerging awareness that the range of both classroom assessments and accountability assessments needs to be extended (Hill and Barber, 2014).

Specifying 21st century competencies

There is no universally agreed definition of 21st century competencies. A large number of relevant frameworks exists (for example, Ananiadou and Claro, 2009; Bereiter and Scardamalia, 2012; Binkley et al., 2012; Birenbaum, 1996; Chalkiadaki, 2018; Conley, 2003, 2005, 2010, 2011; Cook and Weaving, 2012; de Corte, 2010; Dumont and Istance, 2010; European Union, 2019; Gordon et al., 2009; Partnership for 21st Century Skills, 2019; Pellegrino and Hilton, 2012; Voogt and Roblin, 2012; Wagner, 2008; Wang

et al., 2018; World Education Forum, 2015). While these frameworks reveal differences of perspective, terminology and emphasis, there are substantial conceptual similarities, and a collated framework can be constructed, consisting of the following domains (Maxwell, 2021, pp. 80–85):

- Domains of knowledge (or domains of learning, or substantive learning)
- Information and communication technologies (ICT)-related competencies
- Conceptual competencies
- Cognitive competencies
- Metacognitive competencies
- Personal (or Intrapersonal) competencies
- Interpersonal competencies.

Each of these domains is made up of a variety of components or dimensions indicating different characteristics of the domain. These components can be represented as separate learning aims and assessable competencies.

Domains of knowledge (domains of learning)

Knowledge domains or disciplines remain the main organizers of curriculum in most countries and are seen as foundational for all 21st century competencies (Australian Curriculum, Assessment and Reporting Authority, 2019; Binkley et al., 2012; European Union, 2019). Knowledge domains typically include the arts and humanities and science-technology-engineering-mathematics (STEM), as well as other specialized areas of knowledge (Partnership for 21st Century Learning, 2019; UNESCO, 2013), and sometimes also literacy and numeracy. While domains of knowledge are not themselves usually conceived as competencies, they are the sites where most competencies are realized, and need to be mentioned for this reason. Some 21st century competencies assume specific characteristics within each knowledge domain; others may be cross-curriculum (“transversal”), that is, perhaps developed within several knowledge domains but transferable to other situations with a different knowledge base.

Information and communication technologies (ICT)-related competencies

These are sometimes seen as defining a knowledge domain in itself, or otherwise as cross-curriculum competencies. Three sub-domains can be identified:

- ICT literacy (technical skills for accessing and using digital technologies and communication tools)
- Information literacy (capabilities for accessing, managing, evaluating and using information)
- Technological literacy (understanding the ways in which technologies can be used to solve complex problems)

Conceptual competencies

Different facets of knowledge can be categorized as factual, conceptual and procedural (Krathwohl, 2002). Factual knowledge encompasses the terms, definitions and elements that define a field of knowledge. Conceptual knowledge encompasses understanding and includes theories, principles, ideas and ways in which facts can be organized and related. Both of these are concerned with knowing “what”. Procedural knowledge encompasses techniques and procedures, that is, knowing “how”. In the classification of competencies, factual knowledge is not included, perhaps taken for granted as foundational within domains of knowledge. In the classification of competencies here, conceptual knowledge competencies and cognitive competencies offer a different division and elaboration of conceptual and procedural knowledge. The main issue is that, while factual knowledge provides the “component parts”, their integration and application is essential for building a meaningful and useful knowledge “engine”.

Conceptual competencies represent desirable qualities for conceptual knowledge, and typically include:

- conceptual depth and complexity
- structuring and interconnection of key concepts
- working with abstractions (connecting theory and practice through abstract modeling)
- transferability (capability of applying knowledge learned in one context to another context).

Cognitive competencies

These may also infuse the knowledge domains or else be treated as cross-curriculum competencies. They typically include:

- higher-order thinking skills (understanding, analyzing, interpreting, evaluating, generalizing, organizing, structuring)
- problem solving and problem formulation (hypothesizing, strategizing, experimenting, investigating)
